

Vol. XXV. — 1906.

INDEX TO AUTHORS' NAMES.

N.B. — This Index (P) indicates that the matter referred to is an abstract of a Patent. Where the letter P follows the number of a page, it indicates, in the case of a patent, that a reference only to a previous patent appears on that page; in the case of articles other than patents, the title only of an article will be found on such pages. The titles of new books are given within quotation marks.

	PAGE		PAGE
A. J. G. Coke, ammonia, gas, tar, benzol, &c., Production of — by distilling carbonaceous materials (P)	468r	Act.-Ges. f. Anilinfabr. — <i>cont.</i>	
dy, J. See Macatone, T.	582	Malonyl- <i>p</i> -phenetidine, (d)alkylated derivatives of — (P)	560r
Herhald, H. See Fischer, E.	278	Moistening substances; Process for facilitating — (P)	368
egg, R. See Scholtz, M.	677	Nitro derivatives of aromatic bases; Manufacture of — (P)	64
elli, M. Explosives; Manufacture of — (P)	120	5-Nitro-2-aminophenol and azo dyestuffs derived therefrom (P)	687r
brahan, H. Sulphates; Manufacture of — (P)	1210	A. Pepsin preparation (P)	37r, 194r
Accumulatoren Fabrik A.-G. Lead and silver; Extraction of — from ores (P)	379	Peptone; Manufacture of silk fibroin — (P)	278r, 279r
Aebi, F. See Fischer, E.	232	Phenylanthimidazole; Aminoalkoxy-sulphonic acids of — (P)	1142
Acker, C. E. Tin and chlorine; Producing compounds of — (P)	697r	Phenylanthimidazole; Manufacture of derivatives of — (P)	215, 750, 923r
Acker Process Co., and C. E. Acker Stannic chloride; Manufacture of — (P)	180	Photographic developer; Manufacture of a — (P)	234
Stannous chloride; Manufacture of — (P)	180	Photographic plates, films, &c., and developers (P)	30r
Tin compounds; Apparatus for making — (P)	218	Sensitizing gelatin, gum, &c., for the pigment and similar processes (P)	30r
Tin; Manufacture of chlorine compounds of — (P)	180	Sulphide dyestuff; Manufacture of a — (P)	137r, 424r
Tin; Producing oxygen compounds of — (P)	759	Sulphide dyestuff; Manufacture of an orange — (P)	200r
Ackermann, K., and F. Toggenburg Beer analysis with the refractometer	286	Sulphide dyestuffs; Manufacture of brown — (P)	175
Adams, E., and W. A. Syme Poison; Ivy plant, Constituents of the — (P)	951	Sulphide dyestuffs; Manufacture of yellow to orange — (P)	175, 471r, 530r
J. Anilinfabr. <i>p</i> -Ammobenzole ester; Manufacture of salts of — (P)	335r	Theochrome-barium and sodium salicylate; Preparation of an easily soluble double salt of — (P)	284, 560r
phenolsulphonic acid (P)	174r	Triphenylmethane dyestuffs; Manufacture of — (P)	369, 634r, 844
phenylethersulphonic acid; Manufacture of a — and of azo dyestuffs therefrom (P)	65	Act.-Ges. f. Mechanische Holzbearbeitung A. M. Luther. Wood; Impregnation of — (P)	375
dyestuffs (P)	844r	Adam, A. J. J. — <i>cont.</i> producer (P)	743
dyestuffs for lakes; Preparation of — (P)	922	Adam, P. Milk treated with hydrogen peroxide	331
dyestuffs; Manufacture of blue black mono- — (P)	880	Adam, R. See Möhlau, H.	1037, 1037r
Azo dyestuff, Orange mono- — (P)	1215	Adams, M. J., and J. Cannon Kilns; Construction of pottery — (P)	638
Development of the latent image (P)	867r	Adams, P. H. Ore concentrators, Centrifugal — (P)	1182
Dialkylmalonic acid diamides; Process of making — (P)	197, 559r	Ore separators; Centrifugal — (P)	1152
Dianilidine and diphenetidine; Manufacture of disulphonic acids of — (P)	424, 634r	Adams, W. H., and others. Gas; Manufacture of Hummating — (P)	1139
m-Diarylsulpho-diamides; Nitration of — (P)	585	Gas; Manufacture of producer — (P)	1139
1-2-Dichlorobenzene-sulphonic acids; Separation of nitro-derivatives of — (P)	962	Smeiting Process (P)	1154
Di- and trimethylxanthine, Double salts of — (P)	90r	Administration der Minen von Buchsweller, A.-G. Sodium ferrocyanide; Manufacture of — (P)	73r
Dyeing acetylcellulose or artificial silk made therefrom (P)	692, 1210r	Ageron, J. A., and B. J. M. Beny Carbonic acid; — duct for use in making — (P)	947
Dyeing hairs; Process of — (P)	532	Agostini, E. Flushing soap for textiles, &c. (P)	1180
Dyeing hair, fur, &c.; Process for — (P)	982, 982r	Ahlers, G. F. Dusty slop; Discolored — (P)	804
Dyeing leather; Process of — (P)	283	Ahlström, H., and O. Aschau Turpentine oil; Pinecone fractions of French and American — (P)	427
Dyeing threads or fabrics containing acetylcellulose (P)	692	Alilum, C. C. Acid; Volumetric determination of free — (P)	594
Hexamethylenetetramine borates; Preparation of — (P)	567	Ainley, J. S. Textile fabrics; Washing and squeezing machines for — (P)	371
6-Hydroxy-1-2-naphthimidazole-7-sulphonic acid derivatives (P)	1215	Akeson, A., and Standard Gas and Heating Co. Carburetor (P)	864
p-Hydroxyphenylglyoxal-amide; Production of — (P)	687r	Aktiebolaget S. Orskov Centrifugal machines; Continuous — (P)	1061
Indophenol; Manufacture of an — (P)	922	Centrifugal machines for drying, &c. (P)	1061, 1186
Lakes from azo dyestuffs; Manufacture of — (P)	325, 545r, 897r, 897r, 998r	Dryer (P)	473, 1187r
		Drying apparatus, with device for washing, drying or heating (P)	1144r

	PAGE		PAGE
Aktieselskabet Separator - <i>cont.</i>		American Zinc and Chemical Co. See Day, C. E.	374, 842
Separators, Centrifugal - (P) 9, 166, 301, 322, 331r		American Electric Heating Co. See Day, L. 544, 581, 904, 905	
Separators, Centrifugal - liquid (P) 132, 132, 323r	1230	Ammonal Explosives Ltd. See Marchal	865
and A. J. Friesson Separating apparatus, Centrifugal	1032r	Anderson, H. W. See Kynch, Ltd.	803
and E. A. Forsberg Separators for liquids, Centrifugal - (P)	211	Anderson, J. S. Stilling of iron and iron ore, &c.; Electric	272
and B. Ljungström Separators, Limer for centrifugal liquid - (P)	631r	Anderson, W.	542
Aktieselskabet Burmeister & Wain, Maskin og Skibsværktøjet	86	Anderson, K.	841
See Proline B. A. O.		Andrian, E. O. See B. Andrian, L.	700, 704r
Aktieselskabet Guinng Regenerations Soc. See Steenstrup	940r	Andri, F. Stamping apparatus, Vacuum (P)	420
Alabaster, R. C., and F. H. Wittle Pyrite smelting	124	Andrew, G. See Bore, W. A.	1209
Albright, E., and F. Wessell Galvanoplastic deposits, Separating - Iron metal matrices (P)	80	Andrews, J. D. See Fentress (P)	580
Allrecht, A. J. Pyramider (P)	915	Andrien, A. and Grand, Heating compounds, Azoglomerated (P)	466
Allrecht, H. C. Incandescence mantles, Manufacture of - (P)	877, 1085r	Andrien, P. P. A. Mists, wines, and other acid liquids, Determining total acidity of	202
Allyl Carbollubric Aktiebolag, Acetylene and chlorine, Production of compounds of - (P)	107	Andriuk, K. Molasses, Recovery of sugar from, Utilising the "Schleudersalz" for washing in saccharate	600
Alcock, F. H. Calorimetry of volatile liquids, Discussion Copper - Effect of certain elements on - Discussion	240 653	Andriuk, K. Molasses, Recovery of sugar from, Utilising the "Schleudersalz" for washing in saccharate	1109
Alcohol Synthesen, Ltd. Mineral oil, Rectifying (P) 879r, 921r		Andriuk, K. Molasses, Recovery of sugar from, Utilising the "Schleudersalz" for washing in saccharate	785
Alfeld, F. Lager, Non action of - and its photographic application	173r	Angel, A. and Marchetti, G. Azoxy compounds	805
Alexander, I. Cluses and gelatine, Grading and use of -	158	Angel, A. and Marchetti, G. Azoxy compounds	808
Alexander, P. Compositions, Preparation of aqueous solutions - Rubber, Drying and regenerating	180r 597r	Antony, C. and Magn, G. Hydrogen sulphide, Liquid as a solvent	1010
Alexander, T. W., and F. F. Hobbs Soap making apparatus (P)	707	Apel, H. Gases, especially producer gas, Filtering - (P)	686
Alexander, Katz, B. Stone, Artificial (P)	930r	Apostoloff, S. B. Middlings, Utilisation of initiative - (P)	903
Albare, E. Acetylene, Composition of an	861	Appelby, W. J., and Hollinghurst, F. J. D. Stone, Artificial Manufacture of (P)	1148
Albain Hydrogen peroxide, Preservation of medicinal	860	Appert, I. Glass, Manufacture of window - (P)	181
Albright, W. B. Filter plate (P)	304	Apple, A. C. Coke and gas plant (P)	61
Allen, A. Furnaces (P)	544	Applegarth, I., and Quan, J. R. Orgone, Production of - (P)	302
Allen, C. M. Slag, Saving metal values from - (P) and R. Hagenby Converter, Finishing	185 207	Appleyard, W. See Hays, H. D.	906
See Bagshley, R.	185, 611, 641, 654	Arabid Manufacturing Co. Starch, Rendering capable of swelling in cold water (P)	1r
Allen, G. W. J. Water and other liquids, Apparatus for purifying - (P)	1114	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Allen, J. E., and A. C. Ellis Gas, Manufacture of - (P)	942	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Allen, A. Phosphor gas (P)	942	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Allegre, E. Electrodes, Gas, Air pump electrodes (P)	347	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Allegre, E. Electrodes, Gas, Air pump electrodes for analysing - (P)	136	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Alliance Chemical Co., and O. Oberlander o-Toluenesulphochloride (P)	395	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Allis-Chalmers Co. See Sheridan, T. F.	320	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Allison, O. Modern Violet, Blue 1900, and galloxanone derivatives, Dyeing	691	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Allmann, Svenska Elektriska Aktiebolag, Shaft-humors, Electrically heated	768	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Allner, W. Bansen, Flame, The	211	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Alow, J., and P. Trubault Bismuth, Double salts of -	653	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Alpess, J. T. See Clayton Andine Co.	309	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Alpha Portland Cement Co. See Hitzel, H.	376	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Alcop Process Co. See Mitchell, J. E.	278	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Alt, H. Thionin-gel Bol	752	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Altma, H. Wood, Apparatus for impregnating - (P)	848	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Alpöckel, J. See Act-Gas I. Amhufner,	377	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Aluminiumwulfat, Guteschwein, Aluminium foil, Manufacture of - (P)	850, 852r	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Amat, J. Osmosis, Gaseous - through a colloidal membrane	347	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
American Borax Co. See Blumenberg, H. Jun	180	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
American Chemical Education Co. See Wurtz, H.	584	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
American Education Co. Distilling hydrocarbonaceous substances (P)	921r	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
American Electrolytic Co., and Harmon, W. E. Alkaline process, Mercurial - (P)	370	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
American Foundrymen's Association Cast iron drillings, Standardised -	77	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
American Hydraulic Co. See Bittel, E.	886	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
American Process Co. Screw presses for drying, &c. Continuous - (P)	581	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
American Sintering Co. See Davison, G. L.	221	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
American Steel and Wire Co., and Menker, G. L. Metals, Galvanising - (P)	80	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
American Suction Gas Producer Co., and others Gas producer, Suction - (P)	685, 685, 685	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
See Gerdes, H. S.	842	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
See Sauer, S. F.	842	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
American Sulphuric and Tar Co. See Gilmer, G.	274	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
American Water Purifying Co. Distilling water by the multiple-effect system (P)	652r	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Water purifying apparatus (P)	862r	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
American Wine Co. See Brown, A.	862	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
American Zinc and Chemical Co. See Day, C. E.	374, 842	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
American Electric Heating Co. See Day, L. 544, 581, 904, 905		Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Ammonal Explosives Ltd. See Marchal	865	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Anderson, H. W. See Kynch, Ltd.	803	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Anderson, J. S. Stilling of iron and iron ore, &c.; Electric	272	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Anderson, W.	542	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Anderson, K.	841	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Andrian, E. O. See B. Andrian, L.	700, 704r	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Andri, F. Stamping apparatus, Vacuum (P)	420	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Andrew, G. See Bore, W. A.	1209	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Andrews, J. D. See Fentress (P)	580	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Andrien, A. and Grand, Heating compounds, Azoglomerated (P)	466	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Andrien, P. P. A. Mists, wines, and other acid liquids, Determining total acidity of	202	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Andriuk, K. Molasses, Recovery of sugar from, Utilising the "Schleudersalz" for washing in saccharate	600	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Andriuk, K. Molasses, Recovery of sugar from, Utilising the "Schleudersalz" for washing in saccharate	1109	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Andriuk, K. Molasses, Recovery of sugar from, Utilising the "Schleudersalz" for washing in saccharate	785	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Angel, A. and Marchetti, G. Azoxy compounds	805	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Angel, A. and Marchetti, G. Azoxy compounds	808	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Antony, C. and Magn, G. Hydrogen sulphide, Liquid as a solvent	1010	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Apel, H. Gases, especially producer gas, Filtering - (P)	686	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Apostoloff, S. B. Middlings, Utilisation of initiative - (P)	903	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Appelby, W. J., and Hollinghurst, F. J. D. Stone, Artificial Manufacture of (P)	1148	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Appert, I. Glass, Manufacture of window - (P)	181	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Apple, A. C. Coke and gas plant (P)	61	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Applegarth, I., and Quan, J. R. Orgone, Production of - (P)	302	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Appleyard, W. See Hays, H. D.	906	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Arabid Manufacturing Co. Starch, Rendering capable of swelling in cold water (P)	1r	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5 54
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	5
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	54	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	54
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	4	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	4
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	11	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	11
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	4	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	4
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	8r	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	8r
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	886	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	886
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	1081	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	1081
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	631	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	631
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	652r	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	652r
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	380	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	380
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	408	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	408
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	958	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	958
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	425	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	425
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	909	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	909
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	120, 876	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	120, 876
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	356	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	356
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	578	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	578
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	1106	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	1106
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	596	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	596
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	840	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	840
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	342r, 934r	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	342r, 934r
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	417	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	417
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	92	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	92
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	699	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	699
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	269	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	269
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	538	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	538
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	1001r	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	1001r
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	120r	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	120r
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	806	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	806
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	1169	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	1169
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	1213	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	1213
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	355, 955	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	355, 955
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	849, 1047	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	849, 1047
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	1099	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	1099
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	1148	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	1148
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	854	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	854
Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	223r	Archibald, J. Bess, Microstructure of - Discussion Calorimetry of volatile liquids, Discussion	223r

Oxygen. Compositions for use in preparing — (P)	1219r	and G. B. Kettler. Nitric acid and nitrates. Production of — from nitrogen (P)	847r, 847r
and R. von Forögger. Air. Purifying vitiated — (P)	1169r	Buenning, C. Beverages free from or poor in alcohol. Preparation of — from sterile fruit juices (P)	85
Britton, W. Manganese steel rail. Cast — (P)	269, 1152r, 1154r	Buhr, B. Cementitious material. Treatment of blast-furnace slags to produce — (P)	479r
Steel. Treating manganese — (P)	860r, 852r	Brück, R. Ammonia; Extraction of — from gases (P)	697r, 759r
and Taylor Iron and Steel Co. Manganese steel. Toughening — (P)	209	See also Brück, See F.	
Briscoe, J. T. Screening, straining, and filtering apparatus for fluids (P)	774	Brück, See F. Ammonia from distillation gases; Extracting (P)	43, 62r
Bricker, C., and Heitboeck, G. Iron. Kurlchment of pig — (P)	700	Brunei, L. Antimony and arsenic colours. Manufacture of — (P)	703r, 768
Brisemorel, Caffeine. Derivatives of — and reactions of its glycolytic nucleus	820	Antimony oxide pigment. Manufacture of — (P)	32
British Algin Co. and Ingham, T. Seaweed; Manufacture of products from — (P)	908	Zinc ores. Treatment of complex —; Preparation of zinc sulphate and blende (P)	486, 703r, 906r
British Hosiery and Electrolytic Bleaching Co. Electrolytic apparatus (P)	545r	Brun, G., and Padua, M. Sulphides. Precipitation and solution of metallic —	138
British Submarine Boat Co. See Atteridge, A. H.	1062	Brunot, F. Sewage. Screen for — (P)	555r
Broadley, J. R. See Mundy, H. I. M.	256	Brunton, J. T. Wire; Heat treatment of steel —, particularly of wire for ropes	539
Broadwell, E. C. See Lyons, J. A.	427		
Brode, J. "Stickstoffe; Die Oxidation des — in der Hochspannungsflamme"	96		

LIST OF MEMBERS

1901. Smith, J. Crickshank, 5, The Elms, London Road, Wembley, Middlesex, Technical Chemist.
O.M. Smith, Dr. J. H., Seesrasse 417, Wollishofen, Zürich, Switzerland, Chemical Manufacturer.
1888. Smith, J. Tertius, Richmond House, Plaistow, Essex, Technical Chemist.
O.M. Smith, Jno. W., 7, Brookfield Street, Roslindale, Boston, Mass., U.S.A., Analytical Chemist.
1890. Smith, J. Wm., Solvay Process Co., Syracuse, N.Y., U.S.A., Alkali Works Manager.
1896. Smith, Joseph Kent, 32, Hough Green, Chester, Metallurgical Chemist.
1906. Smith, Robert C., 425, Home Avenue, Oak Park, Ill., U.S.A., Chemical Engineer.
1898. Smith, R. F. Wood, 9, Lower Thames Street, London, E.C., Consulting Chemist.
1890. Smith, Dr. R. Greig, Linnean Society's House, Elizabeth Bay, Sydney, N.S.W., Bacteriologist and Chemist.
1890. Smith, R. Watson, P.O. Box 85, Knight's, Transvaal, S. Africa, Chemical Works Manager.
1897. Smith, Theophilus R., c/o Brotherton and Co., Ltd., Haigh Park Chemical Works, Stourton, near Leeds, Chemist.
1896. Smith, Walter E., 141, Cypress Street, Providence, R.I., U.S.A., Instructor in Chemistry.
1903. Smith, Dr. Warren R., Lewis Institute, Chicago, Ill., U.S.A., Teacher.
- O.M. Smith, Watson, 34, Upper Park Road, Haverstock Hill, N.W., Editor of Society's Journal.
- O.M. Smith, Wilfred, 182, West Street, Glasgow, Chemical Manufacturer.
1896. Smith, Dr. W. Stanley, Bryntirion, Bersham, near Wrexham, North Wales, Brewer.
- O.M. Smithells, Prof. A., F.R.S., The University, Leeds, Professor of Chemistry.
- O.M. Smithers, F. O., Dashedwood House, 9, New Broad Street, London, E.C., Chemical Agent.
1902. Smart, Albert M., 99, John Street, New York City, U.S.A., Analytical Chemist.
1902. Smythe, Jno. A., Armstrong College, Newcastle-on-Tyne, Demonstrator in Chemistry.
1902. Smythe, Dr. J. S., Rantallard, Lance Lane, Waver-tree, Liverpool, Analytical Chemist.
1888. Snape, Dr. H. Lloyd, Balholm, Latham Road, Southampton, Director of Education for Lancashire.
1896. Snegdon, J. jun., Messrs. Snowdon, Sons and Co., Millwall, E., Chemical and Oil Manufacturer.
1900. Sodeau, Dr. Wm. H., 19, East Parade, Newcastle-on-Tyne, Chemist.
1903. Söhlman, Ragnar, Bofors, Sweden, Manager (A. B. Bofors Nobelkrut).
1894. Sohn, Chas. E., 2, Harpur Street, Bedford Row, London, W.C., and (Journals) 126 Hewitt Road, Haringway, N., Analyst.
1906. Solomon, M., 45, Newhall Street, Birmingham, Manager (Carbon Works).
1895. Solvay, Armand, 25, Rue Prince Albert, Brussels, Gérant de la Société Solvay et Cie.
1884. Solvay, Ernest, 43, Rue des Champs Elysées, Brussels, Alkali Manufacturer.
1902. Soma, Prof. H., Higher Technical School, Asakusa, Tokyo, Japan, Professor of Chemistry.
1897. Somerset, H. St. John, jun., Mount Morgan Gold Mining Co., Mount Morgan, Queensland, Australia, Assayer.
1884. Sommer, Adolf, corner 1st and Binney Streets, East Cambridge, Boston, Mass., U.S.A., Pharmaceutical Chemist.
1903. Sommermeier, Edw. E., 1590, Neil Avenue, Columbus, Ohio, U.S.A., Chemist.
1894. Sonstadt, Edw., Church Fields, Cheshunt, Herts., Chemical Technologist.
1904. Southall, A. W., Lower Priory, Birmingham, Manufacturing Chemist.
1896. Souther, H., 440, Capitol Avenue, Hartford, Conn., U.S.A., Chemical and Metallurgical Engineer.
1904. Southerton, F., 49, West Grove Road, St. Leonards, Exeter, Teacher of Chemistry.
1892. Southern, Thos., Wheathill Chemical Works, St. Simon Street, Salford, Manufacturing Chemist.
1883. Soward, A. W., 28, "Therapia" S.E., Principal Clerk (Legacy).
1896. Sowerby, Thos. H., Canal Soap Road, Rotherhithe, S.E., Soap.
- O.M. Sowerby, W. M., c/o United Alkali Works, Gateshead-on-Tyne.
1887. Spackman, Chas., Rosolough, Cliffe, Portland Cement Manufacturer.
1904. Sparke, Archibald, Public Library and Bury, Lancs., Chief Librarian, &c.
1904. Sparre, Fin, 1810, Washington Street, Del., U.S.A., Chemist.
1901. Sparrow, J. Marcellus, c/o Imperial Colour Co., Ltd., 6-22, Morse Street, Canada, Varnish and Colour Manufacturer.
1904. Spayd, Chas. Hay, Fernwood P.O., Edgemoor, Delaware Co., Pa., U.S.A., Analyst and Chemist.
1904. Speilen, C. C., 181, Front Street, New York City, U.S.A., Chemical Merchant.
1905. Speight, W. E., Sewage Works, Deighton, Huddersfield, Cheshire.
1883. Spence, D., Manchester Alkali Works, Manchester, Alkali Manufacturer.
1900. Spence, Howard, (Journals) Audley, Broad Road, Sale, Cheshire, and Alkali Works, Manchester, Chemical Manufacturer.
1883. Spence, Jno. W., Tivoli Colour Works, Manchester Road, Stockport, Dyestaller.
1903. Spencer, A. Gordon, Trinro, N.S., Canada, Chemist.
1906. Spencer, Fred W., c/o Standard Ammonia Co., Ltd., Glebe Point, Sydney, N.S.W., Australia, Works Manager.
1884. Spencer, Jno., Globe Tube Works, Wednesbury, Tube Manufacturer.
- O.M. Spencer, J. W., Newbiggin House, Keaton, Newcastle-on-Tyne, Steel Manufacturer.
1901. Spencer, Robt. jun., 3, Woodville Terrace, Bradford.
1902. Sperry, Elmer A., 100, Marlborough Road, Prospect Park South, Brooklyn, N.Y., U.S.A., Electrical Engineer.
1897. Sperry, Erwin S., P.O. Box 656, Bridgeport, Conn., U.S.A., Metallurgist.
1905. Speyer, Jas., c/o Speyer & Co., 21, Pine Street, and (Journals) 257, Madison Avenue, New York City, U.S.A., Banker.
1906. Speer, J. Spafford, Box 401, Emporium, Pa., U.S.A., Chemist (Powder Works).
1884. Spiegel, Dr. Adolf, Messel, bei Darmstadt, Germany, Analytical Chemist.
1903. Spielmann, P. E., 21, Cadogan Gardens, London, S.W., and (Journals) Freudenbergrstr. 30, Zürich, Switzerland, Chemical Student.
1906. Spies, V. G., Middlepark, Kampen, Central Provinces, India, Chemist.
1889. Spies, Adolph, 102, Finchchurch Street, London, E.C., Chemical Merchant.
1889. Spies, Hermann, 102, Finchchurch Street, London, E.C., Chemical Merchant.
1885. Spiller, A., Edison-Swan Electric Co., South Benwell Works, Newcastle-on-Tyne, Electrician.
- O.M. Spiller, J., 2, St. Mary's Road, Canonbury, London, N., Consulting Chemist.
1896. Speer, J. L., Rede Court, Rochester, Kent, Portland Cement Manufacturer.
1906. Springer, Dr. Ail., 312, East Second Street, Cincinnati, Ohio, U.S.A., Chemist.
1900. Spurge, Edw. C., 619, Buffalo Avenue, Niagara Falls, N.Y., U.S.A., Chemist.
1901. Spurlin, Oscar L., c/o Georgia Cotton Oil Co., 919, Austell Building, Atlanta, Ga., U.S.A., Chemist.
- O.M. Squire, P. W., 413, Oxford Street, London, W., Pharmaceutical Chemist.
1896. Stafford, Chas. H., c/o The Birkenhead Printing Co., Chorley, Lancs., Colourist.
- O.M. Stahl, Dr. K. F., 57th Street and A. V. Ry., Pittsburgh, Pa., U.S.A., Chemical Works Manager.
1905. Stahl, Dr. Paul G., 12, Square de Jussieu, Lille (Nord), France, Chemical Manufacturer.

1892. J. C. Bryant Street, Buffalo, N.Y., U.S.A., Colour Chemist.
1900. Stalham, Otto, 317, McCormick Building, Salt Lake City, Utah, U.S.A., Metallurgical Engineer.
1900. Stamp, Edward, Florence House, Dewarup Lane, Dinkinfield, Sewage Works Manager.
1904. Standfast, Jno. T., c/o Messrs. Burt, Boulton, and Haywood, Ltd., Selznick, Belgium, Chemist.
1905. Stanley, Harry, 3, St. Michael's Park, Bristol, Lecturer on Applied Physics and Engineering.
1906. Stanley, Wm., Great Burlington, Mass., U.S.A., Engineer.
1888. Stantial, Frank G., c/o Cochran Chemical Co., Everett, Mass., U.S.A., Technical Chemist.
1885. Staples, H. J., The Old Hall, Spaldon, Derby, Colour Manufacturer.
- O.M. Stark, J. F., Rosedale, Bromborough, Cheshire, Works Superintendent.
1896. Statlam, Noel, c/o The West Virginia Paper and Pulp Co., Piedmont, West Va., U.S.A., Engineer.
1904. Stauffer, W., 64, Oberwiesenstrasse, Basle, Switzerland, Chemical Works Manager.
1895. Stead, J. Christopher, 1, Finsbury Circus, London, E.C., Technical Chemist.
- O.M. Stead, J. E., F.R.S., 11, Queen's Terrace, Middlesbrough-on-Tees, Analytical Chemist.
1906. Stebbins, Chas. H., 76, Meridian Street, Melrose, Mass., U.S.A., Assistant Chemist (Boston Navy Yard).
- O.M. Stebbins, Dr. J. H., 27, East 22nd Street, New York City, U.S.A., Analytical Chemist.
- O.M. Steedman, R. H., Whitfield, Prestwick, Ayrshire, N.B., Chemical Manufacturer.
1896. Steel, Fred. W., c/o Cuning, Smith and Co., Yarraville, Melbourne, Vic., Australia, Chemist.
1900. Steel, Jno. S., Achenart, Blackburn, Melbourne, Vic., Australia, Chemist.
1884. Steel, R. Elhart, 38, East Park Parade, Northampton, Headmaster.
1906. Steel, S. J., 17, Great Tower Street, London, E.C., Analytical Chemist.
- O.M. Steel, Thos., Colonial Sugar Refinery, O'Connell Street, Sydney, N.S.W., Australia, Sugar Chemist.
1906. Steers, Thornton, 221, Grand Avenue, Brooklyn, N.Y., U.S.A., Chemist.
1906. Steiger, George, Cosmos Club, Washington, D.C., U.S.A., Chemist.
1897. Stein, Sigmund, 214, Upper Parliament Street, Liverpool, Sugar Refinery Manager.
1897. Stenhart, Dr. Oscar J., c/o Messrs. Stenhart Vogel & Cloud, 4 Lloyds Avenue, Fenchurch Street, E.C., Manufacturing Chemist.
1903. Stell, S. F., 25, Henry Street, Kewley, Yorks., Teacher of Chemistry.
1887. Stenhouse, T., Townhead, Rochdale, Analytical Chemist.
1903. Stephan, Geo. B., c/o Larkin Soap Co., Buffalo, N.Y., U.S.A., Perfumer.
1904. Stephen, A. E., Lachlan Gold Fields, Ltd., Forbes, N.S.W., Australia, Analytical Chemist.
1884. Stephens, H. Chas., M.P., Avenue House, Finchley, N., Ink Manufacturer.
1892. Stephens, M. E., 4, Carlton Gardens, London, S.W., and (Journals) 57-60, Aldersgate Street, London, E.C., Ink Manufacturer.
1889. Stern, Arthur L., Southbank, Stapenhill Road, Burton-on-Trent, Brewing Chemist.
1906. Steinberg, Frank J. N., 18, Tyndall Avenue, Toronto, Canada, Analytical Chemist.
- O.M. Stemart, D. R., Osborne Cottage, Broxburn, West Lothian, N.B., Oilworks Chemist.
1903. Steven, A. B., The University, Leeds, Lecturer on Dyeing.
1899. Stevenot, G. A., c/o H. A. Metz Co., 1, North Clark Street, Chicago, Ill., U.S.A., Chemist.
1898. Stevens, Arthur F., 96, Newgate Street, London, E.C., Paper Examiner.
1904. Stevens, Edgar B., 688, Seventh Street, Buffalo, N.Y., U.S.A., Chemist (Wood Products Co.).
1902. Stevens, Dr. Hy. P., Laboratory, 15, Borough, London Bridge, S.E., Consulting Chemist.
1894. Stevens, Jno. H., 205, Ferry Street, Newark, N.J., U.S.A., Manufacturing Chemist.
1902. Stevens, M. White, H.M. Patent Office, Chancery Lane, London, W.C., Chemist.
1903. Stevens, T. R. B., P.O. Box 120, Kalgoolie, West Australia, Metallurgical Chemist.
1884. Stevens, Wm., The Native Gum Co., Ltd., 29, New Bridge Street, London, E.C., Secretary.
1907. Stevenson, Chas. F., 80, Polwarth Terrace, Edinburgh, Dyer.
- O.M. Stevenson, Sir Thos., M.D., Guy's Hospital, London, S.E., Chemical Lecturer.
- O.M. Stevenson, W., Standard Works, 95A, Southwark Street, London, S.E., Chemical Manufacturer.
1901. Stewart, David B. D., Aberdeen Comb Works, Hutchison Street, Aberdeen, Managing Director.
1903. Stewart, Jas. 3, Ludgate Circus Buildings, London, E.C., Editor ("Gas World").
1890. Stewart, Robt., 43, Leagrave Road, Luton, Chemical Works Manager.
- O.M. Stewart, S., c/o Michael Nairn and Co., Ltd., Kirkcaldy, N.B., Technical Chemist.
1906. Stickland, Oliver W., c/o The New Explosives Co., Ltd., Stowmarket, Suffolk, Works Chemist.
1904. Stieglitz, Julius, University of Chicago, Chicago, Ill., U.S.A., Associate Professor of Chemistry.
1904. Still, John T., 60, Parrock Street, Gravesend, Kent, Works Chemist.
1903. Stilwell, Albert G., 36, Gold Street, New York City, U.S.A., Chemist.
1903. Stinglein, Dr. Fritz, c/o Solvay Process Co., Syracuse, N.Y., U.S.A., Chemist.
1886. Stark, Jos., Seaside Hydro, Southport, Brewer's Engineer.
1893. Stock, F. W., Keating, County Analyst's Office, Dairlington, Analytical and Consulting Chemist.
1900. Stockdale, Edgar, c/o E. Dewhurst and Co., Ltd., Printworks, Batley, Yorks., Colour Mixer.
1888. Stockdale, Wm., Rosebank Printworks, Ramsbottom, near Manchester, Colour Printer.
1887. Stocks, H. B., 12, Victoria Road, West Kirby, Cheshire, Analytical Chemist.
1903. Stoddard, Jesse D., Detroit Testing Laboratory, 1111, Union Trust Building, Detroit, Mich., U.S.A.
1885. Stoddart, F. Wallis, Grafton Lodge, Stoney Park, Bristol, Analytical Chemist.
- O.M. Storr, J., 6, Hanover Quay, Dublin.
- O.M. Stoker, G. N., 9, Lassar Avenue, Clapham Common, S.W., Analytical Chemist.
1899. Stokes, All. W., Laboratory, Town Hall, Paddington Green, W., Public Analyst.
1906. Stokes, Francis J., 17th and Chestnut Streets, Philadelphia, Pa., U.S.A., Manufacturing Chemist.
1898. Stokes, Dr. Henry N., Bureau of Standards, Washington, D.C., U.S.A., Chemist.
1892. Stone, Frank, Laboratory, 193, Colindale Street, Melbourne, Victoria, Analytical Chemist and Assayer.
1900. Stone, Geo. C., c/o New Jersey Zinc Co., 71, Broadway, New York City, U.S.A., Engineer.
1899. Stone, I. F., 100, William Street, New York City, U.S.A., Chemical Merchant.
1888. Stone, Thos. W., Chemical Works, St. George, Bristol, Chemical Manufacturer.
- O.M. Storey, I. H., Haverbreaks, Lancaster, Chemical Manufacturer.
1903. Stotner, Edward J., c/o Case Threshing Machine Co., Racine, Wis., U.S.A., Analytical Chemist.
1902. Storr, Bertram V., 61, Balfour Road, Ilford, Essex, Chemist.
1888. Stowe, W. T., 11, Camphill Avenue, Langside, Glasgow, Analytical Chemist.
1904. Strange, Edward, Halford, 7, Staple Inn, Holborn, London, Technical Research Chemist.
1905. Strange, Wm. Wallace, jun., Reduction Works, Anaconda Copper Mining Co., Anaconda, Montana, U.S.A., Chemist.
1883. Strangman, J. Pim, Bleacher.
1906. Straus, Loms, 18, West 83rd Street, New York City, U.S.A., Merchant.

LIST OF MEMBERS

1903. Strayer, D. W., 428, West King Street, York, Pa., U.S.A., Chemist.
1903. Strickler, Emerson H., c/o General Chemical Co., 25, Broad Street, New York City, U.S.A., Chemist.
1905. Strunz, Dr. C. E., 1437, Champa Street, Denver, Colo., U.S.A., Chemist.
1906. Strunz, F. B., 672, Summit Avenue, St. Paul, Minn., U.S.A., Chemical Engineer.
- O.M. Stuart, C. E., 29, Mosley Street, Newcastle-on-Tyne, Chemical Apparatus Dealer.
1905. Stuart, H. E., 176, Purchase Street, Boston, Mass., U.S.A., Vice-President, Mercantile Corporation.
1896. Stuart, Harry T. B., Know Mill House, Entwistle, near Bolton, Printworks Sub-Manager.
- O.M. Stuart, T. W., 7, Livingston Drive, Setton Park, Liverpool, Alkali Works Manager.
1901. Stuart, Dr. W. Theophilus, 197, Spadina Avenue, Toronto, Canada, Physician and Professor of Chemistry.
1896. Stubbs, Augustus J., 59, Calle de Ferraz, Madrid, Spain.
- O.M. Studer, Dr. A., Postgebäude, Olten, Switzerland, Consulting Chemist.
1890. Studer, Simon J., Helvetia, Stockton Heath, near Warrington, Technical Chemist.
1903. Sturrock, Capt. G. C., R.A., Aruvankad, Nilgiris, India, Assistant Superintendent.
1896. Suckert, Dr. J. J., 141, Broadway, New York City, U.S.A., Manufacturing Chemist.
1895. Sudborough, Dr. J. J., University College of Wales, Aberystwith, Lecturer in Chemistry.
1889. Sulman, H. L., 44, London Wall, London, E.C., Chemist and Metallurgist.
1895. Summers, Bertrand S., c/o The Summers Fiber Co., Port Huron, Mich., U.S.A., Electro-Chemist.
1890. Sumner, Harold, Worthington, near Wigan, Dyer and Blender.
1896. Sunderland, A., 84, Hamworth Wood Road, Ingrow, Keighley, Teacher of Chemistry.
1899. Sundström, Carl, c/o Solvay Press Co., Detroit, Mich., U.S.A., Chemist.
1895. Sundström, Karl J., Sibley, Mich., U.S.A., Manufacturing Chemist.
1906. Sufermeister, Edwin, Cumberland Mills, Mame, U.S.A., Chemist.
1884. Sutherland, D. A., 13, Victoria Street, and (Journals) 26, Victoria Street, Westminster, S.W., Consulting Technical Chemist and Assayer.
1894. Sutherland, Geo., Croft Cottage, Bonhill, N.B., Chemist.
1887. Sutherland, Jas., c/o British Aluminium Co., Ltd., Larne Harbour, Co. Antrim, Ireland, Chemist.
1906. Sutherland, John, The British Aluminium Co., Ltd., Baker Street, Greenock, N.B., Manager of Carbon Factory.
- O.M. Sutherland, R. M., Lanie Wharf Chemical Works, Falkirk; and Solsgrith, Dollar, N.B., Chemical Manufacturer.
- O.M. Sutton, Dr. Francis, Norfolk County Laboratory, Redwell Street, Norwich, Analytical Chemist.
1886. Sutton, F. Napier, 6, Grosvenor Gardens, Willesden Green, N.W., Alkali Works Inspector.
1900. Sutton, W. Lincoln, Hillcroft, Eaton, Norwich, Public Analyst.
- O.M. Swan, Sir Jos. W., F.R.S., 58, Holland Park, London, W., Chemist and Electrician.
1898. Swanson, Jas. F., 5, Edmiston Terrace, Copland, Govan, N.B., Technical Chemist.
1906. Sweet, Everett F., 33, Broad Street, Boston, Mass., U.S.A., Importer.
1905. Swenarton, W. Hastings, Broadway Chambers, 277, Broadway, New York City U.S.A., Patent Lawyer.
1884. Swinburne, Geo. (Journals), 99, Queen Street, Melbourne, Australia; (subs.) c/o Jno. Coates and Co., Suffolk House, Laurence Pountney Hill, E.C., Gas Engineer.
1904. Swindells, Seth, 181, Orford Lane, Warrington, Chemist.
1901. Swinton, Ralph S., c/o W. J. Bush, Incorporated, Linden, N.J., U.S.A., Analytical Chemist.
1903. Sykes, Harne, F., Cardiff, Analyst.
1902. Sykes, Herbert, 62, Sydney, N.S.W., Australia, Analytical Chemist.
- O.M. Syme, W. B., Elm Cottage, Addiewell, West of Scotland, N.B., Oil Works Chemist.
1906. Symes, Langford P., Parcora Freezing Works, Timaru, New Zealand, Chemist.
1903. Symmes, Whitman, 2231, Piedmont Avenue, Berkeley, Cal., U.S.A., Chemical Engineer.
1906. Symonds, Abram E., Wick Lane Colour Works, Old Ford Road, Bow, E., Colour Manufacturer.
1905. Szegő, A. S., 60, Bewsey Street, Warrington, Chemist.

T

1895. Taber, G. H., 814, Frick Building, Pittsburg, Pa., U.S.A., General Manager (Gulf Refining Co.).
1896. Takagi, T., Kyoikuhin, Seizo Kaisha, Asakusa, Shikibucho, Tokyo, Japan, Chemical Engineer.
- O.M. Takamatsu, T., 13, Nishikitamachi, Hongo, Tokyo, Japan, Analytical Chemist.
- O.M. Takamine, Dr. Jokichi, 521, West 179th Street, New York City, U.S.A., Engineer.
1890. Takayama, Jintaro, Nando Machi 26, Ushigome, Tokyo, Japan, Director (Imperial Industrial Experiment Station).
1905. Talliot, Prof. Henry P., Mass. Institute of Technology, Boston, Mass., U.S.A., Professor of Inorganic Chemistry.
1903. Talbott, Dr. B. E., Chaucer ville, Md., U.S.A., Manufacturing Chemist.
1898. Tanaka, Keisaku, Matsuba Hotel, Kudansaka, Uye, Tokyo, Japan, Chemist.
1906. Tanaka, S., 4, Uratnakashimacho Nishime, Yokohama, Japan, Chief Chemical Engineer (Electric Wire Works).
1900. Tankard, Arnold R., 82, Lanthewy Road, Newport, Mon., Analytical Chemist.
- O.M. Tate, F. H., 9, Hackins Hey, Liverpool, Analytical and Technical Chemist.
- O.M. Tatlock, J., 45, Rentrew Street, Glasgow, Laboratory Furnisher.
- O.M. Tatlock, R. R., 11, Bellshagh Road, Kelvinside West, Glasgow, Consulting Chemist.
1902. Tatters, Hugh Lee, 19, Birchfield Road, Widnes, Analytical Chemist.
1906. Tattersfield, Frederick, The Hollins, Dewsbury, Yorks, Analyst.
1905. Tausig, Dr. Hugo, 237, East 72nd Street, New York City, U.S.A., Chemist.
1905. Taveau, René de Mortener, 1218, Mount Royal Avenue, Baltimore, Md., U.S.A., Research Assistant, Johns Hopkins University.
1898. Taverner, W., Ashland, Oregon, U.S.A., Analytical Chemist.
1901. Tayler, Jno. Bernard, Anglo-Chinese College, Tientsin, North China, Chemist.
1903. Taylor, Alvin M., c/o General Chemical Co., Station F., Box 12, Cleveland, Ohio, U.S.A., Chemist.
1902. Taylor, Arthur P., c/o John Taylor and Co., 531, Front Street East, Toronto, Ont., Canada, Soap Manufacturer.
1902. Taylor, Edward R., Penn Yan, N.Y., U.S.A., Manufacturing Chemist.
1902. Taylor, Francis O., c/o Parke, Davis and Co., Detroit, Mich., U.S.A., Analytical Chemist.
1886. Taylor, G. Crosland, Ravenscar, Helsby, near Warrington, Electrical Engineer.
1894. Taylor, G. Midgley, Gaxton House, Westminster, S.W., Analytical Chemist.
1893. Taylor, G. W., Dinting Vale Printworks, Dinting, near Manchester, Printworks Chemist.
- O.M. Taylor, H. E., 702, Alexandra Parade, Dennistoun, Glasgow, Lead Works Manager.
1883. Taylor, Jas., Nymagee, N.S.W., Australia, Government Metallurgist.

- iii. **Livingston, Liverpool, Wm. J. 322, Bayant Works, Litherland, Liverpool, Chemist.**
- Taylor, J. Scott, North London Colour Works, Spring Place, Kentish Town, N.W., Technical Chemist.**
- Taylor, Martin, "The Clough," Buckhurst Hill, Essex, Chemical Works Manager.**
- Taylor, M. J., 77, Front Street East, Toronto, Canada, Soap Manufacturer.**
- Taylor, Sidney H., 65, Newbridge Road, Weston, Bath, Works Chemist.**
- Taylor, Tom, jun., Journals to Kent House, Sale, Cheshire; communications to Cornbrook Chemical Co., Ltd., Stockport, Colour Manufacturer.**
- 1898. Taylor, Walter, 29, Canning Street, Bury, Lancs., Technical Chemist.**

- 1905. Thresh, Dr. John C., Chelmsford, Essex, Medical Officer of Health and Sanitary Expert.**
- 1902. Thurlow, Nathaniel, 78, Warburton Avenue, Yonkers, N.Y., U.S.A., Chemist.**
- 1898. Thurman, Dr. Gustav, c/o Aurora Metall Co., Aurora, Ill., U.S.A., Chemist.**
- 1904. Thurston, Azor, Grand Rapids, Ohio, U.S.A., Chemist.**
- 1905. Tichenor, Henry D., 18, Exchange Place, New York City, U.S.A., Custom House Broker.**
- 1904. Tickle, Thos., Laboratory, 83, Queen Street, Exeter, Analyst.**
- 1903. Tighe, Arthur, Springfield, Darlinghurst Road, Sydney, N.S.W., Australian, Chemical Student.**

LIST OF MEMBERS.

1901. Tilden, Philip S., c/o Franklin H. Kalbfleisch Co., Metropolis Building, Broadway and 16th Street, New York City, U.S.A., Manufacturing Chemist.
- O.M. Tilden, Prof. W. A., F.R.S., The Oaks, Murray Road, Northwood, Middlesex, Professor of Chemistry.
1900. Tilley, Jas. W., 95A, Southwark Street, London, S.E., Research Chemist.
1906. Tilleon, Henry E., 75, Abbott Street, Lawrence, Mass., U.S.A., Dyer.
1901. Timmans, W. O., c/o Basford Chemical Co., Basford, Nottingham, Chemical Works Manager.
- O.M. Timmis, T. Sutton, Widnes, Chemical Manufacturer.
1905. Tindall, W. B., 30, St. Mary Street, Toronto, Canada, Secretary and Treasurer.
1894. Tipler, Fred. C., 48, Brooklyn Street, Crewe, Analytical Chemist.
1907. Tischbein, Dr. Robert, The Heyden Chemical Works, Garfield, N.J., U.S.A., Chemist.
1890. Tobey, C. H., Barks Falls, Ontario, Canada, Tannery Chemist.
1894. Toch, Maximilian, 52, 9th Street, Long Island City, N.Y., and (Journals) 320, Fifth Avenue, New York City, U.S.A., Chemist.
1886. Todd, A. M., 204, North Rose Street, Kalamazoo, Mich., U.S.A., Manufacturing Chemist.
1905. Todhunter, B. E., West Hydraulic Engineering Co., 23, College Hill, London, E.C.
1906. Tolman, Frank S., 451, State Street, Flushing, N.Y., U.S.A., Superintendent, Oakes Manufacturing Co.
1905. Tolson, Stanley, c/o The Elastex Co., Ltd., North Kent Works, Eltham, Chemist and Factory Manager.
- O.M. Toms, F. Woodland, States Analyst's Office, St. Heliers, Jersey, Analytical Chemist.
1902. Tone, Frank Jerome, c/o The Carborundum Co., Niagara Falls, N.Y., U.S.A., Manager.
1899. Tonic, Jay E., 1427, Woodland Avenue, Des Moines, Iowa, U.S.A.
1896. Tonkin, John, 2603, East Broad Street, Richmond, Va., U.S.A., Manufacturing Chemist.
1902. Torrey, Charles A., jun., Security Life Deposit Vaults, Boston, Mass., U.S.A., Chemist.
1905. Torrey, Prof. H. A., Harvard Chemical Laboratory, Cambridge, Mass., U.S.A., Assistant Professor of Chemistry, Harvard University.
- O.M. Towers, J. W., Widnes, Lancashire, Analytical Chemist.
1892. Townsend, Chas. W., 19, Crawford Street, Port Dundas, Glasgow, Chemical Manufacturer.
1892. Townsend, Oliver C., 22, Heston Crescent, Rugby, Chemical Manufacturer.
1897. Towse, Walter, 31, Malvern Street, Newcastle-on-Tyne, Technical Chemist.
1904. Toyne, Francis D., 270, Spotland Bridge, Rochdale, Chemist.
1905. Trainer, David, 43, Exchange Place, New York City, U.S.A., Agent (Orford Copper Co.)
1890. Trantom, Dr. Wm. Hawthorne Lodge, Litchford, near Warrington, Chemist.
1894. Traphagen, Dr. Frank W., Colorado School of Mines, Golden, Colo., U.S.A., Professor of Metallurgy and Assaying.
1900. Traquair, Jno., Glenfield Starch Works, Paisley, N.B., Analytical Chemist.
1904. Trautwein, Alfred P., Carbondale, Pa., U.S.A., President (Carbondale Chemical Co.).
1906. Truvell, Norman E., 26, Forest Road, Nottingham, Lace Dresser.
1905. Truvell, Chas. L., United Printing Machinery Co., 240, Summer Street, Boston, Mass., U.S.A., Mechanical Engineer.
1893. Travers, Prof. Morris W., F.R.S., Indian Institute of Science, Bangalore, India; and (communications) c/o J. Lyon and Co., 4, Lombard Court, London, E.C., Professor of Chemistry.
1889. Trechmann, A. O., Halting Lane and Cement Works, near Rochester, Kent, Cement Manufacturer.
1885. Trechmann, Dr. C. O., Warren Cement Works, Hartlepool, Cement Manufacturer.
1895. Tréharne, F., Cardiff, Anal.
1885. Trewhay, Herbert, 62, St. John Street, London, W., Analytical Chemist.
1901. Trigger, Oliver, Chem. Dept., Royal Arsenal, Woolwich, S.E., Analytical Chemist.
1898. Tripp, Dr. E. Howard, The Modern School, York Toronto Science Master.
- O.M. Trobridge, A., c/o Trobridge & Co., Ltd., Hewley, Leek, Shore, Felling-on-Tyne, Technical Chemist.
1897. Trotman, Saml. R., The City Laboratory, 1, Regent Street, Nottingham, City Analyst.
1906. Trotz, Johan O. E., 311, Mann Street, Worcester, Mass., U.S.A., Consulting Engineer.
1904. Trubek, M., Wood Ridge, Bergen County, N.J., U.S.A., Manufacturing Chemist.
1900. True, Percival E., 279, Douglas Avenue, Elgin, Ill., U.S.A., Chemical Engineer.
1887. Tsukiyama, S., 2nd of No. 2116, Fukiaicho, Kobe, Japan, Paper Mills Chemist.
1894. Tucker, Alex. E., Norwich Union Chambers, Congreve Street, Birmingham, Metallurgist and Chemist.
1897. Tucker, Samuel A., Columbia University, New York City, U.S.A., Tutor in Industrial Chemistry.
1886. Tuer, Arthur H., Thornhill, near Wigan, Analytical Chemist.
1903. Tutts, C. G., c/o Semet-Solvay Co., Syracuse, N.Y., U.S.A., Chemical Engineer.
1907. Tutts, John L., 15, Park Avenue, Winchester, Mass., U.S.A., Chemical Engineer.
1901. Tulloch, Wm. F., 7, West George Street, Glasgow, Merchant.
1901. Tunnell, Raymond W., 425, West Walnut Lane, Germantown, Philadelphia, Pa., U.S.A., Manufacturer.
1899. Turnbull, Dr. Andrew, Manchester and Liverpool District Tanners' Federation, 3, Lord Street, Liverpool, Consulting Chemist.
1884. Turnbull, G. W., 2, Haws Hill, Carnforth, Lancashire, Metallurgical Chemist.
1905. Turnbull, John, 66, Jarvis Street, Toronto, Canada, Manufacturer of Food Products.
1901. Turnbull, R. H., c/o MacAndrew and Forbes Co., Camden, N.J., U.S.A., Analytical Chemist.
1884. Turnbull, W. S., 37, West George Street, Glasgow, Chemical Manufacturer.
1902. Turner, Basil, 5, Moore Street, Sydney, N.S.W., Australia, Metallurgist.
1902. Turner, Jos., c/o Read Holliday, and Sons, Ltd., Huddersfield, Chemist.
1905. Turner, Prof. Thomas, Springfield, Upton Road, Selly Park, Birmingham, Professor of Metallurgy.
1897. Turney, Fred. N., Saventham, near Brussels, Belgium, Leather Dresser.
1887. Turney, Sir J., Trent Bridge Leather Works, Nottingham, Tanner.
1906. Tuttle, Dr. Franklin E., 125, East Maxwell Street, Lexington, Ky., U.S.A., Prof. of Chemistry.
1903. Tutton, Henry Ralph, 19, St. James' Parade, Bath; and (Journals) 12 Ivy Street, Penarth, S. Wales, Chemist.
1905. Tutwiler, Carrington C., 1706, North Broad Street, Philadelphia, Pa., U.S.A., Chemist.
1890. Tweedy, Jas., 306A, Burdett Road, Limehouse, E., Metallurgical Chemist.
1905. Twigg, Geo. F., 29, Fairfax Road, Derby, Gas Works Chemist.
1891. Twitchell, E., Wyoming, Ohio, U.S.A., Candle Works Manager.
1897. Twynnam, H., c/o Mount Morgan Gold Mining Co., Mount Morgan, Queensland, Australia, Mining Engineer.
- O.M. Twynnam, T., Wyngard House, Coatham Road, Redcar, Yorks., Metallurgist.
1904. Tyler, Chas. R., c/o Dr. Francis Wyatt, 402, West 23rd Street, New York City, U.S.A., Analytical Chemist.
- O.M. Typke, P. G. W., Lawn House, New Malden, Surrey, Chemical Manufacturer.

INDEX OF SUBJECTS.

N.B.—In this Index, (P) indicates that the matter referred to is an abstract of a patent.

Where the letter *r* follows number of page, it indicates that a reference only to a previous patent appears on that page; or, in the case of matter other than patents, that the subject is only referred to by title.

Regenerating — (P) Kreseritzky	29	organic. Preparation of anhydrides of monobasic — (P) Vereinf. Chem. Ind	392, 608
Accumulators; Active material for — (P) Jeanlaud ..	992	organic; Solubility and specific rotatory power of solu- tions of — Holty	328
with alkaline electrolyte, Peroxidising and forming positive plates for — (P) Gouin	545	organic. Preparing alkali salts of — from nitriles and amides (P) Benta Gold-u-Silber-scheide Anst.	1067
Electric		Sucroclastic action of — as influenced by salts and non-electrolytes Gahlwell	1177
(P) Leitner	379	Tubes for concentrating — (P) Krell	847, 927 ^r
(P) Warren and others	992	<i>p</i> -Acridylamino- <i>o</i> -aminophenols; Preparation of —, and their derivatives (P) Meister, Lucius and Brünling ..	369
Use of vanadium and its compounds in — (P) Bonfort	127	Aconite root, Alkaloidal valuation of — Caesar and Lorenz	202
Acetaldehyde; Action of sodium sulphite on — Lum- ière and Seyewetz	89	Variability in potency of — Chevalier and Bardet ..	565
Determination of — Seyewetz and Bardin	202	Aconitine and aconiline from <i>Aconitum napellus</i> . Schulze ..	606
Acetanilide and formaldehyde; Condensation products from — (P) Kille and Co.	283	Reaction of — Monil	1171
Preparation of —, Frencois	281	Actinium, New product from — Hahn	559
Acetic acid fermentation. Buchner and Gaunt	999	Acyl groups of esters of polyhydric alcohols; Removal of — by hydroxyl ions. Kremann	866
manufacture; Separating and working up magnesium sulphate obtained in — (P) Harroway	477	Adansonia fibre, Swedish kraft paper from —, Bendis and Stevens	440
Preparation of — from acetylene (P) Jouas and others	496	Address from the Society of Chemical Industry to Sir Wm. H Perkin	784
from wood and sawdust (P) Orliavaer Chem. Fabrik. 117		Adhesive, Manufacture of — (P) Castile	84
Acetic anhydride, Stability of aqueous and alcoholic so- lutions of — Lumière and Barbier	908	Manufacture of — from waste sulphite lyes: (P) Pntch	195
Acetic bacterium; Morphological-biological investigation of a new — Fuhrmann	648	(P) Robeson	1115
ferment; Composition of an — Allard	861	Ageing dyed fabrics, Process of — (P) Vogel and Calmore	262
Acetification; Apparatus for automatic — (P) Royer 194, 387 ^r	386	fabrics; Apparatus for — (P) Mather and Platt, Ltd. and Smith	586
Acetifying apparatus. (P) Frings	196	Agglomerates for building purposes (P) Lahour	21
Acetone, Action of — on alkali sulphites. Rothmund ..	100	for fuel. (P) Le Maître	842 ^r , 973 ^r
Determination of —	500	Agglomerator; Vertical — (P) Westlake	418
Auld	687 ^r	Agglutinant; Combustible — for briquetting. (P) Le Maître and others	10, 842 ^r
Jolles	684	Agitating apparatus for use in evaporating, distilling, &c. (P) Clark	1080
Manufacture of — (P) Pinget and Camus	684	device for metallurgical apparatus (P) Devereux	320
Manufacture of — from wood and sawdust. (P) Orliavaer Chem. Fabrik	117	electrolytic solutions. Apparatus for — (P) Clarke ..	766
Microbe which produces —, Hércaudnt	640	and mixing apparatus (P) Treat	8, 581 ^r
Acetyl group, Displacement of — by methyl group by diatomethane Herzog and Tschatschek	558	solutions employed in electrodepositing metals (P) Canning and Co.	30 ^r
Acetylcellulose; Dyeing threads or fabrics containing — (P) Act. Ges. f. Anthofabr	692, 1216 ^r	Air; Apparatus for re-oxygenating — for respiration. (P) Bamberger and others	656 ^r
Acetylene burners, Incandescent —, Leeds	682	compressing — (P) Windhausen	167
Causes of explosions with —, Caro	1138	conductivity of — in contact with oxidising sub- stances Jorissen and Ringer	696
and calcium carbide Vogel	114	Constituent producing electric conductivity in — passed over phosphorus. Schenck and others	585
Combustion of — by oxygen Beaupré	114	Cooling and drying large volumes of — continuously. (P) Maschinenbau Anstalt Hünboldt	270, 1080 ^r
Occurrence of calcium hydride in — Hoffmeister ..	114	Determination of carbon monoxide in — by iodine anhydride Levy and Péroul	201
Preparation of ethyl alcohol from — (P) Jouas and others	495	Determination of chloroform in — Sidoux	201
Production of acetic acid from — (P) Jouas and others	496	Determination of nitric oxide in —, Le Blanc	839
Purification of — (P) Joubert	116, 684 ^r	Drying — (P) Lambert	305
Reactions of — with acidified solutions of mercury and silver salts Nienland and Maguire	840	drying apparatus: (P) Cooke and Kelly	166
Reaction of — on iodine anhydride Joubert	91	(P) Williams and Federal Gas Co.	1136
storing — (P) Hubert	876	Drying — for supply to blast furnaces, converters, &c. (P) Hesketh and Wilcox	25
Acetylene chloride; Manufacture of — (P) Prucht	443 ^r	Electrical production of nitrates from — Thompson ..	185
and chlorine, Production of compounds of —: (P) Alby Carbidefabrik	197	Electrically treating — (P) Bridge	1053, 1053
(P) Licholm	718 ^r , 1067 ^r	which extinguishes flame; Analysis of —, Dicoat ..	654
Acetyl-methylcarbinol; Production of — Hardon and Walpole	490	Liquefaction of — (P) Mewes	478
Acetyl-salicylic acid; U.S. Customs decision on —	335	Liquefaction of — and production of oxygen. (P) Mewes	180
Acid anhydrides, Making organic — (P) Sommer	39 ^r	Liquefying apparatus. (P) Pictet	923
Acid; Determination of free — in tan liquors. Hoppen- stedt	1009		
Volumetric determination of free — in presence of iron salts. Abhum	894

Codone; Conversion of thebaine into —, Knorr and	
Horlein	494
Coffee extracts; Preparation of — (P) Koerner	387
Maturing and improving — by oxygen or ozone. (P)	
Desvignes	387
Preparation of — free from caffeine. (P) Meyer	903, 903r
substitute; Manufacture of — from grain or malt.	
(P) Kathreiner's Malzkaffee Fabr.	194
Coherer-powder; Explosive — (P) Schneider	40r
Coke briquettes; Manufacture of — (P) Zanderhoek	684r
Comparison of Rhens-Wesphalian foundry and	
blast-furnace —, Wüst and Ott	761
Manufacture of —	
(P) Armstrong	849
(P) Logan	1083, 1083r
(P) Shaddock	581
Manufacture of dense — from coal dust. (P)	
Pistorius	803
Manufacture of — from fuel containing much water.	
(P) Wichandt and Torfkoks Ges.	870
oven	
(P) Bolde	975
(P) Hily	1033
(P) Jones	1138
(P) Ledoux and Simon-Carves Co.	840
(P) Koppers	12, 468r
(P) Oberbayerische Kokswerke	10, 917r
(P) Pierboni and Bufano	309
(P) Rothberg	840r
ovens; Coking coal in — (P) Otto and Co.	422
ovens; High temperature — (P) Ippolito	975
ovens; Horizontal — (P) Klome	309, 747r, 1082r
oven for peal. (P) Wickham and others	879
oven; Recovery — (P) Clere	1211
ovens; Regenerative — (P) Coppé	468, 580r
ovens with regenerator action. (P) Collin	422r
plant. (P) Apple	61
Production of — from coal dust. (P) De Vena	116
Production of — by distilling coal and other car-	
boneaceous materials. (P) Aarts	468r
production of the United States	840

	PAGE		PAGE
Coke—cont.		Combustion—cont.	
Utilisation of waste heat in — (P) Waddell and Waddell	870	products: Elimination of carbon dioxide from — (P) Whang	918
Coking apparatus (P) Kennedy	1084	of pulverulent fuel (P) Moore	927
coal in coke ovens. (P) Otto and Co.	422	of refuse: Apparatus for forcing — in destructor furnaces. (P) Aslett	652
Process of — (P) Lowe	528	Regulating — (P) Larsen	804
(P) Merrill	867	Commerce Act regulations: Australian —	1123
Colchicine: Determination of — Panchaud	957	Committéed materials: Discharging — from retorts, crucibles, &c. (P) Soc. Anon. des Fonderies et Laminoirs de Blache-St. Vast	850
Cold: Production of — for industrial purposes. (P) Grmolin-Sanson	874	Commission on Canals and Waterways: Royal —	238
Collodion: Compression of — by solvents for artificial silk (P) Soc. Anon. Plaques et Papiers Phot. A. Lumière et ses fils	691	Committee on Industrial Diseases	1062
Filter-press for — (P) Lumière et ses fils	691	on International Exhibitions	1070
Preparation of concentrated — for artificial silk. (P) Lumière et ses fils	691	Composition resistant to water and chemicals. (P) Mönning and Co.	16r
products: Manufacture of — (P) Fabr. de Sole Artificielle de Tubize	1001	Compressed gas: Production of — for use as motive force. (P) Eilen	11
Pumps for supplying — to filters and drawing apparatus. (P) Desmarais and others	333r	Compressing air: Apparatus for —	419
threads: Manufacture of — (P) Denis	1144r	(P) Barker and McConnell	420
Colloidal gold solutions: Formation of — with essential oils Vaino and Hartl	559	air or gases	
precipitates. Washing — Duchaux	806	(P) Gill	523
solutions: Action of electrolytes on — Burton	1122	(P) Meyersberg	305
solutions. Electrical preparation of — Svedberg	543	(P) Windhausen	167
Colloids: Absorption of gallic acid by organic — Dreaper and Wilson	545	Concentrating acids: Tubes for — (P) Kiell	847, 927r
Action of organic — in electrolytic copper deposition (P) Müller and Balmigie	484	apparatus (P) Vind	305
Behaviour of — in sewage. O'Shaughnessy and Kinnerley	710	apparatus for liquids (P) Kestner	1137
Detection of — Winkelsch	1177	deposits from ore crushing (P) Hutclings	378
of opposite electric sign. Mutual precipitation of — Des Banels	852	liquids (P) Montupet and Jannin	840
Separation of — by filtration. Bechhold	1177	liquids and semi-liquids. (P) Tholén	524r
Colophony: Composition of American — Levy	1057	machines for ores and similar substances. (P) Wynne	126r
Manufacture of dry soap from — (P) Bonxami	596	material of all kinds. (P) Murel	874
Colorimeter for determining carbon in steel White	1007	minerals or ores. See under Minerals and Ores.	
Colour bases: Soluble products from salts which higher fatty acids and acids of the oleic series form with (P) Meister, Lucius and Brünig	639r	solutions by freezing. (P) Monti	113
compound resistant to light and weather (P) Hoffmeyer and others	33	solutions and obtaining and conveying salts. (P) Hargreaves	587
distributor for making tapestry. (P) Stömer	692	sulphuric acid: Apparatus for — (P) Dallard	1116
Formation of — by bacteria in saccharine nutrient media Kosowicz	330	Concentrator for solutions. (P) Lloyd	112
photography. See under Photography, &c.		Concrete: Leonard	590
of wort and beer. Determination of — with iodine solutions. Brand and Jaks	640	Flow of under pressure: Woolson	785
Colouring materials: Automatic extractor for — (P) Jury	327, 508	Mixing — (P) Hatis	423
Colouring matter: Apparatus for supplying — to paper making machines (P) Tittel	87	reinforced. Effect of moisture on — Maynard	985
Compounds applicable as — (P) Liechtenstein	130	Condensation mist: Prevention of — (P) Ephraim	257
of distilled liquids: Ascertaining the origin of — (P) Marsh and Weissleder	338	products from aldehydes and negatively substituted acetic acids (P) Knevenagel	392
from molasses, vinasse, &c. Wichard	687	Condenser: Fractional — for steam: Golding	674
in paste: Use of carbon tetrachloride for detecting forbidden — Platt and Bentivoglio	1168	for separating tar in gas works (P) Cie pour l'Éclair. des Villes	1015
for producing silk-like effects (P) Lilienfeld	1143r	Condensing apparatus (P) Brown	303
Prohibition of use of injurious — in Austria-Hungary	857	apparatus for milk, &c. (P) Kaunertmann	1000r
Colours: Chemistry of artists' — in relation to their composition and permanency Thomson	325	gases or vapours: Process and apparatus for — (P) Mottly and Philadelphia Cyanide Process Co.	592
for fabric printing: Production of metallic or lustrous — (P) Lilienfeld	372r	Method of — (P) Eoghe	112
Manufacture of antimony and arsenic — (P) Brunet	768	Conditioning machine (P) Lormer	211, 419r
Manufacture of oil — (P) Hönssou	434r	Conducting films: Manufacture of — (P) Edison	642
Production of — from antimony sulphide and oxy-sulphide. (P) Savigny and Douxami	708	Conductors: Composition for electric — (P) Parker	604, 976r
Silicate — (P) Barth	1220	Clark Electric Co.	695
See also under Paints and Pigments.		Electric — of metallic sodium (P) Bietta	695
Columba root: Alkaloids of — Gadamer	1115	of loosely-packed small pieces for heating resistances. Brown	765
Columbo root: Alkaloids of — Günzel	906	Conifer oils. See under Oils, essential	
Combustible: Artificial — (P) Engle	308	Conifers: Resin acids of the — Vesterberg	82
brquette: Manufacture of agglomerated — (P) Blenaimé and Beguer	115	Couline, nicotine and sparteine: Differentiation of — Reichard	200
Calorific value of — Arth	1138	Synthesis of — Ladenburg	826
Determining heating power of — (P) Junkers	1034r	Contact material: Support for — (P) Soc. Franç. de l'Éclair. par le Gaz.	308
Gasifying and superheating liquid — (P) Heinrich	920	substances: Treatment of — (P) Kitzee and Hamilton	594
liquid for internal combustion engines (P) Oppenheimer	1034r	Converter (P) Walker	221
matter: Determination of volatile — in coals and lignites. Sommermeier	870	Finishing — (P) Allen and Dagdaley	25r
from refuse and coal or charcoal. (P) Reuenaux and Perrier	170	Converting mattes and speisses: Apparatus for — (P) Haas	1051
rich in water: Semi-carbonisation of — (P) Oberbayerische Kokswerke	10	Coolers for powdered or granular material. (P) Matcham	803
See also under Fuel.		Cooling apparatus. (P) Churidge	59
Combustion gases under pressure: Apparatus for producing — for motive power. (P) Vout	307	apparatus for beer, &c. (P) Clew, and West and Co.	710
Method of — (P) Bender	465r	apparatus for liquid soaps. (P) Roth	324r
Process of condensing — (P) Doherty, and Combustion Utilities Co.	538	apparatus for soap, &c. (P) Boardman	434r
products: Apparatus for generating — under pressure (P) Beck	212	brewers' worts: Apparatus for — (P) Daniel and Thornley	439
		fluids (P) Kneiler and Schumacher	1200
		fluids: Apparatus for fractionally — (P) Lambert	8
		liquids: Apparatus for — (P) Barham	7
		Copallin balsam: Neutral preparations of — (P) Knoll and Co.	608
		Copallin oil. See under Oils, essential.	
		Copal: Extraction of — (P) Groppler	1107
		Rendering Manila — insoluble in oil, for polishes, &c. (P) Baringer	703r
		Copals: Action of naphthalene on — Colligier	939
		American — Colligier	1226
		Properties of — Butler	81

Copper; Action of sulphuric acid on ———. Sluiter	318
Action of xanthic leucamines on ———. Slomnesco	895
alloy. (P) Chaudrol	592r
alloys; Casting ———. (P) Fowler and Beak	851
alloys; Microstructure of ———. Jacobsen	883
-aluminum alloys. (P) Incagnoli	482
-cadmium alloys. Salmen	640
castings; Production of dense homogeneous ———. (P) Lab. f. Chem. Feuerschutz u. Löschmittel	990
decadizing ———. (P) Yuncik	889
deposit in Ontario	699
deposition; Action of organic colloids in electrolytic ———. Müller and Balntje	484
Determination of oxygen in ———. Archibutt	42
Determination of ——— by titanium trichloride. Rhead	1175
Effect of certain elements on the structure and properties of ———. Hurns	616
Effect of ——— in steel. Wigham	480
Electrolytic determination of ———. Foerster	1007
Electrolytic preparation of matte from copper matte as anode and acid copper sulphate electrolytes. (P) Borchers and others	188r
Electrolytic production of ———. (P) Borchers and others	433r
Electrolytic recovery of ——— from solutions. (P) Comba and Casper	937r
Electrolytic separation of ——— from nickel. (P) Hyblinette	595r
Electrometallurgical extraction of ——— from minerals. (P) Junnu	39
electrotypes; Manufacture of ———. (P) Cowper-Coles	485
Extraction of ——— from burnt pyrites residues. (P) Tixier	322, 767r
Extraction of ——— from ores. (P) Conedera	935
(P) Sweeting	607, 927r
hardening. (P) Plumer, and Renstrom Tempered Copper Co.	485, 989
Influence of small quantities of elements on ——— upon its reactions with nitric acid. Stausbac	642
in iron. Weddell	45, 1071
Manufacture of pure ———. (P) Junnu	1221
manufacture and refining; Comparison of English and American methods of ———. Platten	892, 1155
matte; Loss of copper and silver in refining ———. Gühler	449
matte; Roasting ———. Gmeling	931
matte; Smelting. (P) Kemp and Kemp Hydrocarbon Furnace Co.	376
refining in Chile	1051
refining in Japan	887
-nickel alloys; Manufacture of ———. (P) Monell	814
-nickel-nickelzinc alloy. (P) Driver	221
-nickel matte; Refining. (P) Hyblinette	764
Treatment of ———. (P) Johnson	26, 379r
clearance of ——— in thick mass sludge. Bulow	481
ores; Electrolytic treatment of ———. Storgor	818
ores; Fluxing ———. (P) Baggeley	706
ores; Lixivation of ——— by ferrous chloride or sulphate solution. (P) Froelich	1157
-palladium alloys. Rier	20
and phosphorus. Heyn and Bauer	379
-plating iron. Electrolytic ———. Brown and Mathers	1150
Power of ——— to form alloys with pure iron and iron-carbon alloys. Pfeiffer	1047
Recovery of ——— from ores. (P) Knubold and others	545
Recovery of ——— and other values from ores. (P) Lovett	703
Refining ———. (P) Baggeley and others	325
refining furnace. (P) Baggeley	592
refining with silicon or silicides; Attempts at ———. Hoyer	185
Regeneration of electrolyte in extracting ——— from bronze. (P) Throat and Mage	26, 20
residues; Electrolytic treatment of ———. (P) Lafontaine	698
residues; Italian Customs decision	892
Separation of bismuth from ———. Staelier and Scharfenberg	856
separation process. (P) Elliott	931
slimes; Treatment of ———. (P) Thomson and Lalat	41
smelting; Constitution of mattes produced in ———. Gibb and Philp	320
Solidification of ———. Dejean	1051
-steels. Breuil	24
and sulphur. Heyn and Bauer	813
Tensile overstrain and recovery of ———. Morley and Tomlinson	608, 886
Volumetric determination of ——— with potassium iodide. Cantoni and Rosenstein	370
Wet extraction of ———. (P) Seagle	318
Copper acetate. U.S. Customs decision on ———	1233
-alkali-cellulose. Norrman	816
-calcium acetate; Manufacture of a double ———. (P) Pontus	121
-cellulose as fabric for incandescence mantles. Byrno	662
chloride; Reduction of ——— by calcium. Backspill	759r
hydroxide; Apparatus for preparing ammoniacal ———. (P) Meitz	840
salts in irrigating waters. Skinner	124
silicide. Lebeau	928
	384
	187

Copper—cont.	PAGE
solutions; Purifying ammoniacal ———. (P) Lecœur	808, 984r
sulphate; Conversion of cupric chloride into ———. Darier	(P)
sulphate; Decomposition of ——— by methyl alcohol. Auger	264
sulphate; Electrolytic manufacture of ———. (P) Granier	837
for ———. (P) Dolphin	891r
sulphuric. Manufacture of ———. (P) Abraham	78
sulphuric manufacture; Liquid-distributing apparatus	1219
sulphuric; Refining ——— contaminated with iron salts. (P) Conedera	536
sulphuric solutions; Decomposition of ——— by aluminum alloys. Pechenx	607, 927r
sulphuric; Manufacture of ——— for thermo-electric couples. (P) Cie Thermo-Electrique	318
Copra; Preservation of ———. (P) Marot	854r
Cordite; Determination of moisture in ———. Dupré	702
Direct estimation of nitroglycerin in ———. Suberrad, Phillips and Merriman	780
Protection of steel gins from the erosive effects of ———. (P) Dupp	628
Cords; Producing non-absorbent ———. (P) Malsdell	484
Cork, artificial; Manufacture of ———. (P) Conde	190
compositions; Manufacture of ———. (P) Matas	1004
fabrics. (P) Sechuri, and Soc. Anon. du Grignon	950
Fabrics made by covering leather or rubber with ———. (P) Soc. Anon. du Grignon	181
substitute. (P) Fuchs	691r
Corn; Bleaching and sterilising ——— and its products. (P) Zimmermann and Buchman	821
Cornstalks; Food extract from ———. (P) Mains, and Food and Fibre Products Co.	987
Preparation of blue from ———. (P) Mains, and Food and Fibre Products Co.	387
Corrosive liquids; Spreading or distributing apparatus for ———. (P) Dolphin	774
Cotton; Apparatus for obtaining ——— from waste products. (P) Knopf and others	280
bobbin; Dyeing ———. (P) Fontaine	536
dyeing with sulphide blacks; Pillig's paper on ———. Kertész	310r
dyeing with sulphide blacks; Tending of ———. Pilling	373
fabrics; Mercerising ———. (P) Beresin	310
fibres; Fireproofing ———. (P) Calico Printers' Association	210
impregnated with methylene diamine. (P) Merck	1042
insects which attack ——— in Egypt. Implecon	15, 16
and linen; Test to differentiate ———. Herzog	1144
Machines for treating new ——— with liquids. (P) Milan	531
Moisture in ———. Harlshorne	888
Nitrating apparatus for ———. (P) Wolfshohl	1090
oil; (P) Karmüller	318
Production of fast brown shades on ———. (P) Badische Anilin und Soda Fabrik	893, 828r
residues and fibres from cotton seed husks; Recovery of ———. (P) Mueck and Barth	807
-silk mixture; Production of a ——— which can be evenly dyed. (P) Benberg	217
slubbing; Dyeing and mercerising ———. (P) Sturmer	217
softeners; Composition and properties of ———. Burnham	1042, 1042
Treatment of ———. (P) Burton	295
waste; Centrifugal machine for removing oil from ———. (P) Fischer and others	925
waste; Scouring ———. (P) Favre	1091
Winding ——— on bobbins for dyeing and mercerising. (P) Fontaine	1217
Cottonseed hulls; Treatment of ———. (P) Knopf, and Brenner Baumwollwollen	373, 755
oil. See under Oil, fatty	
pitch; U.S. Customs decision	217
Coumarin from m-cresol. Fries and Klostermann	1100
Council; Report of ———	335
"Crackling gas," from luku crude oil. Engler and Roemer	659
Cream; Dedicating and preserving ———. (P) Révenot and De Neveu	977
Cresotic compounds. (P) Berendes, and Bayer and Co.	36
Esters from ———. (P) Bayer and Co.	827
Crosscutting; Hermetically sealed doors of cylinders or chambers for ———. (P) Danks	827, 1002r
m-Cresol; Coumarin from ———. Fries and Klostermann	580
Crossfield and Sons' works; Visit to ———	335
Crucible. (P) Colby	673
crucibles; Ascertaining the temperature of ———. (P) Rudge-Whitworth, Ltd., and others	934

		c.c.-Dialkyl-2,4-dimino-6-oxypyrimidines. Preparation of — (P) Merck	654
Dairy products. Suction apparatus for — (P) Taylor	194r		
Dammar resin. From Federated Malay States	804		
Datisca cannabina root. Dyestuff of — Kozczynski and Marchlewski	1088		
Datura. Mydriatic alkaloids of the genus — Schmidt	389		
Deacon process. Equilibrium in the — Lewis	1095		
Function of the catalyst in the — Levi and Voghera	927		
Decanting apparatus. (P) Destumaux	113		

	PAGE		PAGE
Dialkylmalonic acid derivatives; Process of making — (P) Meister, Lucius and Brüning	90	Dimethyl sulphate; Behaviour of — towards fatty oils, oil of turpentine and pinoline. Valenta	366
diamides; Process of making — (P) Act.-Ges. f. Anilinfabr.	197, 559r	for determining tar oils mixed with rosin and mineral oils. Valenta	366
Dialkylmalonylureas; Manufacture of — (P) Meister, Lucius and Brüning	90, 233, 443r, 654r	<i>o</i> -Dimethyl-4,6-diamino- <i>m</i> -xylole. Morgan and Clayton	844
Dialkylpyrrolidine derivatives; Preparation of — (P) Bayer and Co.	909	Dimethylxanthine; Double salts of — (P) Act.-Ges. f. Anilinfabr.	560r
1,3-Dialkylpyrogallol ethers; Preparation of — (P) Basler Chem. Fabrik	392	<i>o</i> - β -Dinaphthylazine; Preparation of — (P) Meister, Lucius and Brüning	369
Dialyser for purifying cuprammonium solutions (P) Lescour	925	Dinitroglycerol Volpert	777
Dialysis — Kahlenberg	446	Dinner, Annual —	674
under sterile conditions Brown and others	1135	Dipeptide; Formation of — by hydrolysis of silk-fibrin. Fischer and Abderhalden	278
Diamines; Diazo derivatives of aromatic — Vigon 173, 259		Diphenetidinethiolsulphonic acids. Manufacture of — (P) Act.-Ges. f. Anilinfabr.	424, 634r
<i>p</i> -Diamines and <i>o</i> -naphthol; Indophenols and sulphide dyestuffs from — (P) Rus	175	Diphenyl Black. See under Azo dyestuffs.	
Diaminonaphthalamines Noelling and Wortmann	259	Diphenylbichazoaminobenzenes and diphenylbichazoaminobenzenes. Vigon	584
Diaminonaphthalazines; Preparation of — (P) Meister, Lucius and Brüning	471	Diphenylcampho-methane and -methylenes. Haller and Bauer	558
4,5-Diamino-2-thiooxy-pyrimidines; Preparation of — (P) Merck	443	Diphenylcarbazide. Use of — as indicator in iron determinations Brunt	337
<i>p</i> -Thiaminodiphenylamine; Preparation of — Berber and Sisley	13	Diphenylmethane series. Reduction in the — Duval	214
Diaminoformylphenylamine. Manufacture of — (P) Meister, Lucius and Brüning	13r	Disazo-compounds of <i>p</i> -phenylenediamines. Fatty-aromatic mixed — Butow and Basse	806, 1213
Dianilinoxyethylene. β -Substituted ester of — (P) Bayer and Co.	134r	Discharge. Use of lithopone for obtaining a pure permanent white — (P) Meister, Lucius and Brüning	586
3,4-Diaminoguanacel Mehter and Schwab	1086	Discharges on wool with potassium sulphite Hellmann and Co. and Baldenay	425
Dianisophenol. Development with — Lammere and Seyewetz	496	Discharging agent. Hydrosulphite — (P) Badische Anilin und Soda Fabrik	15
Diamylenediphosphoric acids. Preparation of — (P) Act.-Ges. f. Anilinfabr.	424, 634r	agents. Manufacture of — (P) Badische Anilin und Soda Fabrik	119r
Dianthraquinonimides. Preparation of — (P) Bayer and Co.	175	on coloured grounds (P) Badische Anilin und Soda Fabrik	532r, 1042
Diaphragm, Electrolytic — (P) Roberts	1156	dyed materials and pastes thereof (P) Badische Anilin und Soda Fabrik	474, 807, 1040r
<i>m</i> -Diarylsulphohamides; Nitration of — (P) Act.-Ges. f. Anilinfabr.	585	by hydrosulphites. Process for — (P) Badische Anilin und Soda Fabrik	586r
Di-azaronone Szeki	827	<i>o</i> -Naphthylamine Claret: Kocidin	685
Diastase. Influence of reaction of medium on the activity of — Fernbach	192	Schmetz and Frossard	1039
Preparation of pure — Magneine and Roux	192	Wilhelm	690
Production of pure — (P) Frankel	278	Naphthylamine Claret with sodium hydrosulphite: Baumann and Frossard	370
Diastases. Property of — Duchaux	899	Baumann and Thiessar	176, 473, 689
Diastatic content of malts from large and small corned barley Elfridi	601, 648	Baumann, Thiessar and Hug	176, 371
enzymes. Influence of certain alkaloids on the activity of — Goebel	329	textile fabrics; Pastes for — (P) Badische Anilin und Soda Fabrik	474, 586r
malts extracts. See under Malt extracts		Diseases, industrial. Committee on —	1062
saccharification. Magneine and Roux	601	Diseulcants. (P) Smith and Davis	775
substance (P) Takamine	901	Bacteriological testing of — Lloyd	405
Diazo derivatives of aromatic diamines Vigon 173, 259		from chloromethylbenzene and soap. (P) Schwabe	331
ground. Reserving a black dyestuff printed on a red — Bloch and Zelder	1039	fluids. Preparation of — (P) Schmetz	338
salts. Action of water on — Carr and Norman	173	Formaldehyde — (P) Chem. Fabr. Phleg	1063
Diazoamines; Influence of substitution on formation of — Morgan and Clayton	844	Formaldehyde — (P) Stepan	232r
1,2-Diazoaphthalenesulphonic acids. Manufacture of salts of — (P) Badische Anilin und Soda Fabrik 751, 979r		Formaldehyde as a brewery — Schwegel	35
Diazonium salts; Replacement of negative radicals by hydroxyl in — Noelling and Buttgenay	214	Influence of organic matter on the efficiency of certain — Blyth	555
1,2-Dichlorobenzenesulphonic acids. Separation of nitro derivatives of — (P) Act.-Ges. f. Anilinfabr.	752	from naphthols Schneider	605
Di-electric separators (P) Sutton and others	1105	Standardisation of — Blyth	1183
Diethylacetyldiethylamide. Preparation of — (P) Kalle and Co.	910	in Vietnam	1001
Diethylmalonylcarbonylureas; Manufacture of — (P) Chem. Fabr. von Heyden	283	Disinfecting action. Relation between chemical constitution and — Bechhold and Birken	555
Diffraction gratings. Intensification of glass — Wood	1232	compound (P) Smith, Kline and French Co.	493
Dilasser. (P) Glas	898	purposes. Soap, oil-soluble or paste for — (P) Kessler and Co.	493
Diffusion in jellies. Influence of foreign substances on — Bechhold and Ziegler	822	Disinfection process and apparatus: (P) Gauthier	905
juice; Acidity of — Grosjean	822	(P) Lassabère	388
juice, Purifying — (P) Károly	759	(P) Rouquier	653
processes (P) Ronssean and others	771	Disintegrating machine (P) Mundy, Broadley and Rhodes	256
waste-waters. Return of — to the battery Claassen	327	washing, and screening machine (P) Storey	1152r, 1164
waters. Purification of — (P) Soc. Anon. de Radmerie et Sierrie Say, and Pellet	707	Diss. Manufacture of paper pulp from — (P) Echégot	338
Digallie acid; Barium and calcium salts of — Procter and Bennett	251	Dissolving gases or vapours. Condensing and — (P) Mullis, and Philadelphia Cyanide Process Co.	592
Digester. Wood fibre — (P) Handford, and Wood	88	Distemper. Preparation of — (P) Casin Co. and Church	82
Dihalogenated aliphatic compounds; Preparation of — (P) Merck	393	Distillation. Apparatus for — (P) Breiman and Hlues	901
1,4-Dihydroxyaphthalene alkyl ethers; Manufacture of — (P) Badische Anilin und Soda Fabrik	922, 979r	Apparatus for continuous — (P) Ronats and Simon	9
Di-iminobarbituric acids; Preparation of — (P) Merck	443	of coal, &c. Destructive — (P) Bowring	171, 686r
Di-isopropyl and di-isoeugenol methyl ether. Szeki	827	in high vacuum; Application of Dewar's absorption method to — Wohl and Losanbach	136
Dika fat. Lewkowsch	30	of liquids, Continuous — (P) Fischer	362
<i>o</i> -Diketones; Hydrazones and osazones of some — Landrieu	328	readiness of vinases. Recovery of — (P) Verbeke	947, 947
		Separation of head and tail products in spirit — (P) Pimpé	230
		of sewage sludge and other organic waste, Destructive — (P) Butterfield and Watson	1035
		in <i>vacuo</i> at low temperatures. D'Arsonval and Bardes	1120
		Distilled liquids. Ascertaining the origin of colouring matters present in — (P) Marsh and Weissleder	388
		Distilleries; Evaporators for the spent wash or pot ale of — (P) Lemox and Mackenzie	332

	PAGE
Distillery by-products. Treatment of — (P) Rivière	773
refuse; Treatment of — for the production of fuel. (P) Connell and others	804
refuse; Utilisation of — for briquetting (P) Armstrong	420
slop; Dedicated — (P) Ahlers	604
slop; Treatment of — (P) Roehr	901
washes; Analysis of fermented — Hanow	553
Distilling: Acid-proof vessel for — (P) Luchard	167
apparatus: (P) Ariapal	902
(P) Brown	303
(P) Coxell	604
(P) Dampfessel und Gasometerfabr. vorm. Wicke und Co	921
(P) Klotz and Wagner	482
(P) Pernal	59
(P) Wertz	962, 1114
apparatus, Automatic and continuous film — (P) Clemenger	879
apparatus, Continuous — for benzene, &c. (P) Gerhardt	172r
apparatus for gas liquor, &c. (P) Planck	423
apparatus, Multiple utilisation of heat in — (P) Thoen	8
apparatus for tar, &c. (P) De Cloes's Patent Ges.	1036
apparatus, Vacuum — with automatic cut-off. (P) Robert	874
apparatus for water: (P) Barthelomew and Hill	950
(P) Parker	950
coal and other hydrocarbonaceous substances; Apparatus for — (P) Wirtz, and American Chemical Education Co	584
coal, &c.; Purifying gases produced in — (P) Wilton	747
coal, &c.; Retorts for — (P) Woodall and Duckham	306, 422r 581, 582
hydrocarbonaceous substances. (P) American Chemical Education Co	921r
liquids (P) Montupet and Jannin	849
liquids <i>in vacuo</i> . (P) Unglaub	1032
Method of — (P) Forbes	112
moist materials, e.g. peat, coal. (P) Jabs	843
petroleum (P) Bradford and Treadwell	172
resinous wood; Apparatus for — (P) Pins	171
water by the multiple-effect system (P) American Water-Purifying Co.	652r
whisky. Schudrowitz and Kaye	900
wood; Apparatus for —: (P) Davis and Richardson	939
(P) James	301
(P) Jewett	805
wood; Retort for — (P) Henry	172
Dithionite acid and dithionates; Analysis of — Ashley	1176
Documents; Rendering — transparent and waterproof (P) Crabb	775
Dolomite; Furnace for roasting — (P) Schmatolla	267
Dominica; Experiments with rubber-yielding plants in — Jones	704
Douglas fir, pitch and terpenes of the — Frankforter	1107
Drawings; Rendering — transparent and waterproof (P) Crabb	775
Dressing agents; Decomposition and solution of — Tagliani	752
wool rugs; Lamb.	11
for yarns and other textiles (P) Paechner	1144
Driers for paint, varnish and oil; Colourless. (P) Gattet	1226
Drillings; Standardised cast iron — Amer. Foundry-men's Assoc.	77
Drinks; Compounds for making non-intoxicating — (P) Brodrick	491
Drug trade in 1905 Finney	95
Drugs, Brazilian — Peckolt	712
Dry-cleaning; Home Office Memorandum	1040
fabrics with benzene &c. (P) Weiss	981, 1040r
process (P) Doux	881
Drying air (P) Lambert	305
Drying apparatus. (P) Aktiebolaget Separator	973
(P) Bell	419
(P) Chamberlain	431
(P) Collins	683
(P) McElroy and McElroy	1032
(P) Matcham	462
(P) Meyer	1032
(P) Ochsatz	168
(P) Roysolger	878
(P) Schaffer	59
(P) White and others	1136
Air — (P) Cooke and Kelly	106
for animal or vegetable materials. (P) Stauber	683
for bricks, timber, &c. (P) Hughes	1148
Continuous — (P) Aktiebolaget Separator	1137r
for clay products. (P) Lyle	1148
with device for washing, dyeing, or heating the material. (P) Aktiebolaget Separator	1081, 1144r
for hops, &c. (P) Hort	229
for loose materials. (P) Seidile	745
for malt. (P) Ellermann	491, 1113r
for milk, &c. (P) Kaunermann	1009r, 1009

	PAGE
Drying apparatus—cont.	
Rotary: (P) Pouret	918
(P) Hills	915
for textiles: (P) Mertz	926
(P) Tattersall	1216
Vacuum — (P) Pasaburg	683, 915r
for vegetables, fruit, starch, &c. (P) Yagn	86
for wood, &c. (P) McWhirter	1098

Roasting and desulphurising — (P) Howard	511r
for roasting, drying, or desulphurising ores, &c. (P) Leggo	126, 591r, 591r
for roasting limestone, dolomite, &c.; Gas — (P) Schmidolla	267
Roasting or oxidising — (P) Dewey, and Amer. Zinc and Chem. Co.	842
Roasting and volatilising — (P) Clawson	934
Rotating — for treating ores and combustibles (P) Ducey	890, 990
for separating metals. (P) Letch	699r
Smelting —:	
(P) Koch	1154
(P) McElharr	1154
(P) Rivard	761
(P) Venecobra Mine Equipment Co. and Partridge	221
Smelting, crucible, and other — (P) Incandescent Heat Co. and Smellwood	1049
Smoke-consuming —:	
(P) Fulton	915
(P) Schmut	684
(P) Secher	1139
smokeless; Practical way of building — Foster	404
Solid electrolyte tube — Harler	545
for supplying heated air or gases (P) Clark	387
Tilting — (P) Cromwell, and Garrett-Cromwell Eng. Co.	399
Tilting ore-roasting — (P) Edwards	816
for utilizing special gases (P) Panchen	462
for vertical retorts (P) Derval	747
Zinc — (P) Dor-Delatre	26, 185r, 378r
Fuel oil; Manufacture of —:	
(P) Ehrlich	999
(P) Mohl and Lewin	604r
(P) Eulian and Stern	1000
Production of — In fermentations with sterilized yeast preparations. Prinsheim	1167
Fuses; Aluminium — Schwartz and James	79
Composition for — (P) Uge	40r
Zinc — Schwartz and James	79
Fusing materials by electricity:	
(P) Brindley	1156
(P) Roessler Haasler Chemical Co.	1053

G

Gallena; Treatment of — (P) Kingsley	889
Gallacolein. See under Pyrene dyestuffs	
Gallacetophenone; Condensation derivatives of — Rupe and Velt	468
Gallie acid; Absorption of — by organic colloids. Dreager and Wilson	515
Barium and calcium salts of — Procter and Bennett	251
Gallocyanine dyestuffs: Blue, 1900; Fixing —:	
Pavre	690
Allston	691
Condensation of — with aminonaphtholic acids	
Grandmoulin	634
Fixing — Allston	691
Modern Violet. Fixing —:	
Pavre	690
Allston	691
Galvanisers' waste products; Treatment of — (P) Sanders	265
Galvanizing metals electrolytically. (P) Amer. Steel and Wire Co. and Meaker	80
Galvanophatic deposits; Separation of — from metal matrices. (P) Albit and Wesol	80
Gambler trade of India	1108
Garbage; Fuel from — (P) May, and National Garbage Fuel Co.	61
Reducing — (P) Edson	940, 949

Gas, Air; Apparatus for producing — (P) Robert ..	529
Air; Carburettor for producing — (P) Soc. Le Radlogaz	804
Air; Accelerating combustion of mixtures of — (P) Gasmotoren Fabrik Deutz	11
and air; Apparatus for supplying a uniform mixture of — (P) Arundel and Higginson	753
and air; Explosion of coal — Hopkinson	520
and air mixture; Production of — for lighting. (P) Soc. par Actions pour l'Éclairage Sels	919
Air; Manufacture of uniform — (P) Spork	1212
analysis apparatus:	
(P) Allgem. Feuertech. Ges.	136
(P) Bayer	1120, 1175r
(P) Hartung	561
(P) Morehead	828
(P) Schlatter and Deutsch	285r
(P) Sodeau, and Brady and Martin, Ltd.	554
analysis apparatus; Automatic —:	
(P) Monopol Betriebskontroll-Apparate 394, 629, 778	
(P) Schatz	610r, 715r, 828r
analysis; Incandescent mantle as catalyst in — Mason and Wilson	9
analysis, Sodium hydrosulphite in —	
Apparatus for extracting tar from — (P) Holmes and Cameron	635
Apparatus for producing power —:	
(P) Hertzog and Saurer	877r
(P) Tait, and Combustion Utilities Co.	170
apparatus; Suction — (P) Griffin	582
calorimeter:	
Boys	234
(P) Doherty	635, 812r, 920r
(P) Sargent	421
(P) Stokes, and Stewart and Co	963
calorimeter; Recording —:	
Bain and Batten	505
(P) Bunsley	364
Carbureting — (P) Hamert	877
cleaning, Westgarth	740
cleaning machine. (P) Nordensson and Laird	628
compressed; Producing — for use as motive force (P) Ellen	11
Continuous production of mixed — (P) Hoim	1212
Cyanogen in coal — Sattelbeck	806
engine exhaust gases; Resistance of metals to corrosion by — Dutsch	802
engines; Application of large — in German lion and steel industries. Reinhardt	761
engines built in Great Britain. Westgarth	740
engines; Utilization of waste heat of marine — for producing steam. (P) Caplaque	364
Extracting tar, ammonia, and water from — (P) Feld	529, 919r
fires; Refractory bodies for — (P) Delage	746
furnace:	
(P) Koppers	468r
(P) Ladd	1084
furnace; Regenerative — (P) Siemens	633r
Furnaces or retorts for making — (P) Rammens ..	306r
generating apparatus:	
(P) Eldred, Ellis, and Combustion Utilities Co.	213
(P) Lowe	528
(P) Reid	841r
(P) Shaw and Rhody	918
Generating combustible — from carbonaceous liquids (P) Cotton	1034r
generating furnace. (P) Burzell	685
generating machine. (P) Steurin	306r
generating machine (P) Monitor, and General Patent Promoting Co	527
Generation of — (P) Ellis, and Combustion Utilities Co.	308
Generation of power — (P) Boyd and McKay	1033
generator:	
(P) Bornmann	421
(P) Cochran, and Chicago Title and Trust Co.	1084
(P) Dwechamps	170
(P) Gieseler	747
(P) Jones	633
(P) Kynoch, Ltd.	685r
(P) Parsons	234
(P) Marconnet	841
(P) Maschinenfabr. und Mühlenbauanst. G. Luther	633r
(P) Radcliffe	365r
(P) Towns	365r
generator with automatic ash outlet. (P) Von Kerpely ..	583
Generator for — from closed vessels. (P) Desouches ..	583, 583
generator; Combination of a pair — with a steam generator (P) Guillet	920
generator in direct connection with a burner. (P) Kneuter	308
generator using small or dust-coal:	
(P) Verein Anthracitwerke	116
(P) Weselsky	168
generator furnaces. (P) Benelmans	1033
Generator for — at high temperature and pressure. (P) Castellan	1084
from generators; Means for indicating the quality of — (P) Dillr and Budler	212
Generators for mixed — (P) Bührer Frères	116
generators; Producer — (P) Hutchins and Wildlife	974
Hydrocyanic acid and ammonia from — (P) Feld ..	10r

Gas—cont.	PAGE	Gas producer—cont.	PAGE
Increasing yield of — in gasworks, and revivifying the purifying materials. (P) Blanc and Caton.....	1211	(P) Maschinenfabr. und Mühlenbauanstalt G. Luthar	464
Liquor; Distilling apparatus for —. (P) Francke	423	(P) Morgan	528
Liquor; Extracting ammonia from —. (P) Ellinger	977	(P) Nash	877r
-making for heavy oils. (P) Eveno.....	160	(P) Reuleaux	804

Sichian and Calabrian —	559	Gas-making oils. Composition and valuation of —	169
U.S. census of —	1172	Gas producer for heavy — (P) Brist	916
Verbena oil. Roure-Bertrand	907	Gas producer for heavy — (P) Brist	916
Wood oils; Philippine — Clover	289	Lubricating oils. Constants of mineral — Kissling	977
Wormwood oil. Roure-Bertrand	907	Mineral oil soaps. Manufacture of — (P) Kornblöcher	856
Wormwood plant. Formation and distribution of oil in — Roure-Bertrand	907	Mineral oils. Apparatus for testing — (P) Roth	256r
Wormwood plant; Terpenic compounds in the — Roure-Bertrand	907	Mineral oils. Cholesterol content of — Rakoun	1085
Oils, fatty: Action of ozone on — (P) Molinari and Soncini	1055	Mineral oils; Emulsifying — (P) Kornblöcher	856
Arachis oil from Southern Rhodesia	899	Mineral oils. Manufacture of candles, &c. from — (P) Kress	1141
<i>Arbutus unedo</i> oil. Sam	188	Mineral oils. Manufacture of emulsions of heavy — (P) Van der Ploeg	423, 687r
Bleaching — (P) Metz and Clarkon	1059	Mineral oils. Production of oil-free, wax-like paraffins from — (P) MacGarvey and Stransky	423
Castor oil; Canadian — Liebreich	1054	Mineral oils. Refining —	
Castor oil product; Manufacture of — (P) Oelwerke Stern-Sonnemur	273, 278	(P) Alcohol Syndicate Ltd	879r, 921r
Castor oil from Southern Rhodesia	899	(P) Macalpine and others	584
Characteristics of certain foreign — Schröder	128	Mineral oils. Solidifying and making solid soap from — (P) Kress	1141
Cocconut oil. Reijst	381	Mineral oils forming stable emulsions. (P) Jamnager	1036
Cocconut oil; Alcoholysis of — Haller and Yousonlian	1226	Mineral oils; Working up — (P) Landsberg	634
Cocconut oil in butter. Detection of — Robb	1045	Naphtalin; Apparatus for separating — from oil or other liquids — (P) Edison	787
Cocconut oil in butter. Detection of — by the Polenske method. Fickel and Harrison	870	Naphtalin; Oxidation and distillation of — (P) Soc. Anon. des Combustibles Industriels	680r
Cocconut oil in butter fat. Determination of — Harris	1159	Oil-burning equipment; Simple — De Kalb	114
Cocconut oil; Keeping qualities and causes of rancidity of — Walker	381	Refining and purifying — (P) Day	1035
Cod liver oil; American — Tolman	382	Tar oils; Dimethyl sulphate for determining — Valcota	306
Cod liver oil. Examination of — Timmon and Dunlop	272	Tar oils; Emulsions of — (P) Spitzholz	748r
Cod liver oil. Production of — in Finnmark — Bul	614	Tar oils for impregnating, &c.; Working up heavy — (P) Nördlinger	1036
Cottonseed oil trade of Marschke	1158	Tar oils. Preparation of dermatologically active compounds which do not darken. (P) Knoll and Co	440
Electrical hydrolysis of — (P) Simpson	273	See also Petroleum	
Emulsions; Viscid or fluid — (P) Kisters	767, 857r	Oily matter. Recovery of — from sewage sludge. (P) City of Bradford, Garfield and Grossmann	86
Examination of — Thomson and Dunlop	937	Oniments. (P) Kessler	893r
Extraction of — (P) Geuer and Brandy	81, 893r	Oleic acid. Constitution of — Molinari and Soncini	1055
Fish oils; Composition of certain — Fokin	935	Molinari and Soncini's paper on the constitution of — Harries	1158
Fish oil; Eliminating the odour of — (P) De Hemphill	80, 857r	Ozonides of — Harries and Thieme	1055
Fish oils; Examination of — Thomson and Dunlop	272	Ozonides of — Decomposition products of — Harries and Turk	1158
Fish oil industry of Japan	596		
Gummy material; Production of — from oils. (P) Bore, Tassy et de Roux	894		
Hardening and solidifying — (P) Kronstein	857r		
Herring oil; Japanese — Sage	988

Manufacture of manure from iron — (P) Gerdes.....	540
(P) Van Haften.....	509r, 997r
moss; Manufacture of half-stuff for millboard and paper from — (P) Beresford.....	804
Partly coking — (P) Oberbayerische Kokswerke.....	917r
Production of fuel from — by the electric current. (P) Bessey.....	405r
Semi-coking — (P) Oberbayerische Kokswerke.....	10, 917r
Pecuni. Levi and Willner.....	384
Pedunculus viviparus, the cause of muelage formation in "Weissbier." Schönfeld.....	771
Pendulous; Determination of — Jolles.....	500
Presence of — in scammony root Reguler.....	41
Volumetric determination of — Jolles.....	201
Pepsin preparation (P) Act-Ges f. Anilin-fabr.....	37r, 194r
Peptone; Manufacture of silk fibron — (P) Act-Ges f. Anilin-fabr.....	278r, 279r
preparation containing iron thiocyanate. (P) Baum.....	443
Peptones from casein Skrap and Witt.....	913
Petborates; Manufacture of — (P) Deuts. Gold- und Silber-Schmelz-Anst.....	180r
Petrolates; Electrolytic manufacture of — (P) Coulere.....	271r
Percussion caps; Manufacture of safety — (P) Gehre.....	108
Perkin celebration.....	783, 1207
Presentation to Sir Wu — in America.....	957
Peroxides, Earth alkali and allied — Foregger and Philipp.....	208 (Erratum)
Preparation and purification of — (P) Poulenc.....	374
Packing and storing washing powders containing (P) Königswarter.....	486r
Peroxidised compounds; Manufacture of — (P) Kirchhoff und Neirath.....	884
Peroxydase; Action of — on alcoholic fermentation without cells Bach.....	551
Influence of — on the action of catalase Bach.....	551
Peroxydases as enzymes with specific activities. Bach.....	649
Persian berry colour, U. S. Customs decision on —.....	259
Persian wines; Lecomte.....	946
Persulphates; Electrolytic production of — (P) Telch-nier and Askanasy.....	992r
Pern; Mineral industry of —.....	1100
Vanadium in — Hewett.....	931
Petrol; Vaporisation of — (P) Soc d'Éclair. et de Chauf. par les Proc. A. Guy.....	1033
Petroleum; Apparatus for producing gas from — (P) Green and Merville.....	870
Bleaching the distillation residues of — (Charitach-kow.....	214
Barylaw crude — Wielezyska.....	214
Bromine value of — Utz.....	1140
Weiger.....	1140
Chemical examination of — Charitach-kow.....	467
Compound giving greater brilliancy to illumination by — (P) Mallon.....	467
Determination of water in crude — Gracie.....	1035
distillates and residue; Determination of pitch content of — Charitach-kow.....	1140
distilling apparatus. (P) Dampfessel-u-Gasometer-fabr vorm. Wilcke und Co.....	921
Distilling crude — (P) Bradford and Treadwell.....	172
Egyptian import duty on — reduced.....	12
Elimination of sulphur from — (P) Blackmore.....	117, 117
Extraction of — from bituminous rock. (P) Endrie.....	921
Risks of Trinidad. Craig.....	1140
Illuminating bodies and candles from — (P) Kuess.....	1141
Industry of Roumania.....	588

filtering machines. (P) Hull and Fell	904	artificial; Dyeing ——— (P) Act.-Gen. f. Anilinabr.	602, 1210r
purification; Nitration with reference to ——— Chlick	279	artificial; Machine for dyeing or washing ——— (P) Mertz	981
purification of a ——— O'Shaughnessy	348		
purifying agent. (P) Swallow, Swallow and Filburn	231		
purifying apparatus. (P) Travis	588r		

Silk—cont.

artificial; Manufacture of —:	
(P) Boullier	1217
(P) Crumière	691
(P) Dietl	16, 217r
(P) Fabr. de Soie Artific. de Tubize	1001, 1144
(P) Germann	532
(P) Gorrard	924r
(P) Lukmeyer	120, 692, 1099r
(P) Vittenet	177r, 474, 845, 925r
artificial; Manufacture of brilliant threads of — (P)	
Soc. Gm. de la Soie Artific. Linkmever	692
artificial; Manufacture of — from viscose. (P)	
Soc. Franc. de la Viscose	753r
artificial; Preparation and compression of collodion for — (P) Soc. Anon. des Plaquas et Papiers	
Phot. A. Lumière et ses fils	691
artificial; Producing filaments of — of large diameter. (P) Krafft	1041
artificial; Recovery of alcohol and other to — (P)	
Soc. Fabr. en Italie de la Soie Artific. par Proc. Chardonnet	1144
artificial; Recovery of solvents from bobbins of — (P) Donge	71, 119r
artificial; Rendering — waterproof and non-inflammable. (P) Germann	636
artificial; Spinning machine for — (P) Metz	981
artificial; Treatment of — (P) Soc. Anon. Fabr. de Soie Artif. de Tubize	372
Boiling off, bleaching and dyeing — (P) Schmidt	
Frères	475, 475
Chemical characteristics of "eau" — Gnaoli	687
cotton mixture. Production of a — which can be evenly dyed. (P) Benberg	217
Curling and fraying of dyed — Sansone and Sansone	1215
Determination of weight of — Porsoz	1121
fibres; Water resisting, cellulose coated — (P) Soc. Anon. pour l'Etude Ind. de la Soie Serret	980
fibrin; Formation of a dipeptide by hydrolysis of — Fischer and Abderhalden	278
fibrin; Manufacture of — (P) Act. Ges. f. Auflufabr.	278r, 279r
-like threads; Manufacture of — (P) Friedrich	1040r
Manufacture of brilliant threads similar to — (P) Bayer und Co.	202r
Process of charging — (P) Günoll	632r
Production of photographs on — Farrell	135
rag; Carbonising — (P) Roberts	981r
Rendering — charged with tin compounds resistant to the atmosphere and to perspiration. (P) Soc. Anon. Coop. per la Stagionatura e l'Assaggio delle Sete ed Affini	262
threads; Glossing and gassing machine for — (P) Mann	635, 636r
Treatment of — with theoria (P) Soc. Anon. Coop. per la Stagionatura e l'Assaggio delle Sete ed Affini	262, 1091r
Unzinning and dyeing raw — simultaneously. (P) Gebr. Schmidt	924
Weighted — Guelin and Dürseler	1069
weighted with tin, resistant to light Meister and Grandmoulin	688
Winding — to facilitate treatment with liquids (P) Derré	110r, 1091r
works; Recovery of alcohol and ether in artificial — (P) Dervin	71, 925
yarn; Imitation, U. S. Customs decision on —	261
yarn; Machine for dyeing — (P) Garcl	756
Silicon; Manufacture of refractory bodies from — (P) Thorne	123r
Treatment of — (P) Seabold	182r
Silver alloy. (P) Hobson	78r
Alloys of — with bismuth, thallium and antimony. Petrenko	887
Alloys of — with magnesium. (P) Zencuznyj	639
Determination of — Goldschmidt	338
Determination of — in large quantities of silver coins Holstema	200
Electrochemical extraction of — Vaygomy	891
Electrolytic precipitation of — (P) Snodgrass	1157
Extraction of —	
(P) Comer	329
(P) Holson	851, 851
(P) Slater	1152
Extraction of — from ores (P) Asbeck	988
Galvanometer as indicator in the volumetric determination of — Draper	911
-gold precipitate at Red-Jung-Labong mines, Treatment of the — Truscott	1047
and lead; Extraction of — from ores. (P) Accumulator Fabrik A-G	370
Loss of — in refining copper matte Gunther	981
ores; Amalgamation process for refractory — (P) Huguet	700
ores; Fine grinding in the cyanide treatment of — Brown	182
ores; Francke-Tina process for reducing — Fox	763
-platinum alloys. Thompson and Miller	988
Separation of bismuth from — Stachler and Scharfenberg	41
solvent; Selective — (P) Hobson	851, 889r
Treating ores containing — (P) Blackmore and Howard	988, 1102r

Silver—cont.

Wet extraction of — (P) Seigle	816
-zinc alloys. Petrenko	818
Silver chloride, bromide and thiocyanate; Solubility of — at 100° C. Böttger	808
chloride; Reduction of — by calcium. Hackspill ..	124
chloride; Solubility of — in hydrochloric acid and in sodium chloride solutions. Barlow	1121
erythrostate emulsion; Panchromatic — Mees and Wratten	910
salt solutions; Preparation of pure — (P) Bülsterli ..	180
salts; Reaction of acetylene with acidified solutions of — Nienwand and Maguire	840
Silvered plates; Manufacture of — (P) Martin	1102
Silvering composition (P) Bülsterli	126r
Size; Application of — to paper (P) Lockett and Baker ..	864
Dissolving — for paper making. (P) Kniffler. 441, 441.	441
Manufacture of — (P) Bonnet	942
from resin, &c., Apparatus for making — (P) Bigland	494
Sizing composition for paper making. (P) Soc. Anon. Mirabet	1231r
fabrics; Hot-air drying chamber for — (P) Caquellin	17
of paper; Determining hardness of — Klein	1001
Kollmann	905
for yarn and other textiles. (P) Paschinger	1144
Skins; Absorptive properties of chromed — for tanning. Wood and Holmes	896
Apparatus for dyeing — (P) Martinet and Dulac 693r, 881	
Dyeing and secreteage of — (P) Pichard	1092r
Extraction of glue, grease, &c. from — (P) Harger	597
Extraction of grease and oil from — (P) Brewer and Hardy	328
Manufacture of fur from — (P) Granville	697
Printing in colour on — (P) Dubois	982
Printing tawed or tanned sheep or goat — (P) Sardine	373
Puering or lating — Rogers	108
Tanning — (P) Ziegel	1227
Tanning and deplating — (P) Glasel	770
Treatment of — (P) Klugmann	888r
Slag; Apparatus to determine the melting point of — Johnson	812
Apparatus for making artificial sand from — (P) Hamfeldt and Gubage	270r
Apparatus for pulverising blast-furnace — (P) Colossus	20, 120r, 592r
Artificial stone from — (P) Schumacher	1148
blast-furnace — Boudonard	591
-cement and sea water Maynard	428
Determination of phosphoric acid in basic — by the "micro-mechanical" method. Quarry and Toussaint ..	912
Disintegrating apparatus (P) Kalinowski	541r, 543
Disintegrating molten blast-furnace — (P) Lessing ..	222
Dissolving solid fluxes in fluid — (P) Tinn 593r, 599r	
Generating steam from hot — (P) Mitchell	126
granulating apparatus —	
(P) Clark	764
(P) Hamfeldt	370r
Manufacture of building stone, pipes, and briquettes from — (P) Glin-Mühener Bergwerks Act.-Ver. 760, 1097r	
Manufacture of cement from — (P) Colossus	310r
Material similar to brass from blast-furnace — (P) Colossus	428r
Production of — (P) Benjamin	700
Production of — poor in metallic oxides in manufacture of steel (P) Kleckrodt (L.M.B.H.)	221
Production of vitreous brick, tile, &c. from — (P) Baggaley	181
Reducing iron — by carbon monoxide and hydrogen. Kassel	1099
Relation between hydraulic properties and composition of blast-furnace — Jöcher	760
Saving metal values from — (P) Allen	185
Smelting the — (P) Parry	184
Treatment of — (P) Ridley	479
Treatment of blast-furnace — to produce cementitious material (P) Brulin	479r
Slates; Manufacture or ornamentation of — (P) Kellett and others	590
Slimes; Apparatus for recovering precious metals from — (P) Guyas	269
Treatment of — (P) Thomson and Laist	1051
Small; Defects of — in the salt-glazing kiln. Scheller and Gielz	811
Smelting furnace; —	
(P) McGahan	1154
(P) Rivard	764
(P) Vencedora Mine Equipment Co. and Partridge ..	331
furnaces; Duplex — (P) Lindmann	184r
materials; Process of — (P) Gröbwall	850
ores in blast furnaces. (P) Kemp	270, 816r
ores; Furnace for and process of — (P) Riveroll ..	542
of ores. Iron sand, &c.; Electro — (P) Anderson ..	272

Separating solids from — (P) Ges. f. Abwässerklärung	711, 905r
Water; Anti-catalytic actions of — Bredig and Fraenkel	563
Apparatus for determining oil in feed and other — (P) Morison	362
Apparatus for the electrical purification of — (P) Lester	379
Apparatus for electrolysis — (P) McCarty and Darby	380
(P) Varelle	271r, 700r
Apparatus for examining boiler — while the boiler is in operation (P) Schmitz	195, 885r
Apparatus for purifying —: (P) Allen	1114
(P) Declercq	904
(P) Dunkelberg	402
(P) Griffith	605
(P) Krüger	338
(P) Riech	862
(P) Schmidt	440, 775r
(P) Stephenson	862
Apparatus for purifying — by distillation (P) Amer. Water Purifying Co.	862r
Apparatus for purifying — by electrolysis: (P) Bailey, and Electro-Pura Water Co.	380
(P) Zerbe	281
Apparatus for softening and purifying —: (P) Danks and Danks	1231
(P) Sheuerman and Hand	905, 908
(P) Wollaston	440
Apparatus for treating — with powdered materials (P) Maignen's "Filtre Rapide" and "Anti-Calcaire" Co., and Ellis	270
bacteria; Biology of — Kohn	711
Continuous extraction of — by electro-osmosis (P) Meister, Lucius and Brünig	127r
Continuous removal of sulphuric acid from — (P) Reiser	1000
Copper salts in irrigating — Skinner	584
Decomposing — by electrolysis (P) McCarty and Darby	821, 821r
Determination of oil in boiler feed — (P) Martin	7
Determination of — in crude petroleum. Graefe	1035
Determination of sulphates in drinking — Raschig	285
Determining the turbidity of — Liversage	45
distilling apparatus: (P) Parker	950
(P) Wenz	1114
Distilling — by the multiple effect system (P) American Water Purifying Co.	658r
Electrolytic purification — (P) Electric Water Purifying and Filter Co.	127r

Water—cont.

	PAGE
Electrolytic decomposition of — (P) Darby	937r
filters (P) Bell and Bell	904
Filter for purifying — (P) Milne	187
Introducing reagents for purifying — (P) Overhoff	555
mineral; Apparatus for extracting salts from — (P) Deprin	1147
mineral; Electric resistances of natural and artificial — Negreano	824
Purification of —: (P) Brown, and American Wire Co.	862
(P) Griffith	37r
(P) Grondel frères	863
(P) Kestner	1114
(P) Kniffier, and Vera Chemical Co.	905
(P) Lambert	862, 904r, 1063
(P) Malche	87
(P) Wixford	86, 87, 388
purification: Continuous — (P) Schröder, and Dents, Refrinder-Gesellschaft	132
purification; Electrolytic — (P) Dion, and America Electro-Hermatic Co.	904
purification system (P) Wixford	383
purifier (P) Bastian, and Maschinenfabr. Grevenbroich	87
purifying installations; Lime saturation apparatus for — (P) Eichenauer	652
Purifying and sterilising —: (P) Lavollay	195
(P) Salsruter, and Jean Cie	711
Purifying — by suspended filter-beds (P) Girard and Drapier	1093
receptacles; Composition for preventing incrustation in — (P) Rühert and Rühert	1063
Recovery of fatty matter from — (P) Ges. f. Abwässerklärung	382, 693r
Separation of argillaceous matter from — (P) Horchardt	87
softening; Mechanics of — Royce	452
sterilising and clarifying — (P) Hy	1063
Sterilising — by ozone (P) Ost	1063
Sterilising, softening, and heating — (P) Westrop and Cooper	1063
still (P) Barnstead	711
Water-gas. See under Gas.	
Waterproof compound (P) Nowak and Smith	262
fabrics; Manufacture of — (P) Bond	372r
tissues (P) Bond	318, 586r
Waterproofing cardboard, &c. (P) Haigh and others	906
composition: (P) Lelshman	521
(P) Shepherd	532
felts and other fabrics (P) McKerrow and others	982
fibres, fabrics, paper, &c. (P) Meulders and Bonriet	1092
fibrous substances; Process for — (P) Chem. Fabr. Mörsheim Dr. H. Noerdlinger	475
materials; Process of — (P) Kochmann and Kaufmann	262r
skins and furs (P) Klugmann	855
soft felt hats (P) Maurer	68
solutions: (P) Lederer	326r
(P) Mongauzi	1050
Waterways; Royal Commission on —	238
Wax: Bleaching — (P) Weingärtner	938
of <i>Rhaphia Ruffa</i> . Jumele	433
substitute for making coloured papers (P) Winter	894
Waxes; Treatment of — (P) Braeschler-Kurtz	219
unflammable; Rendering — (P) Boncheton	1056
Weed killer (P) Blackie	605
Weeds; Destroying — in cornfields (P) Gutchard	905
Weight; Apparatus for determining the loss or gain in — during treatment of substances (P) Oxley	91
"Weissler"; Cause of mudclags formation in — Schönfeld	771
Welding iron or steel; Method of and fluxes for — (P) Davies and Clark	699
Western Australian bark. Mann and Cowles	831
Whale oil. See under Oils, fatty.	
Whalebone substitutes; Production of — (P) Poinaisk and Bloom	648
Wheat flour: Bleaching — Flenfont	194
Process of cleaning — (P) Held	554
proteins; Properties of — Chamberlain	1108
Whey; Preparation of — from skim-milk (P) Deutsche Milchwerke	382
Whisky blending (P) Dunbar	85
Determination of esters, aldehydes, and furfural in — Tolman and Trecoot	1167
Distillation of — Schildrowitz and Kaye	900
Removing noxious elements from the higher alcohols of — (P) Hilliard	1168
See also Spirits.	
White lead. (London Chamber of Commerce)	22
Apparatus for making —: (P) Bailey, and United Lead Co.	708, 989
(P) Bost	158
(P) Union Lead and Oil Co.	857

must; Treatment of —. (P) Moot.	115, 999
Wines; Ageing —:	
(P) Desvignes.	388r
(P) Schtcherbakow.	948
Algerian — of the Mascara district. Jalade.	1061
Apparatus for heating or cooling —. (P) Soc. Quelin et Perias.	459
Biological studies on champagne —. Cordier.	602
containing a high percentage of alcohol. Passerini.	1167
Determination of total acidity of —. Andrien.	202
Determination of tannin in —. Kramsky.	93
Electrically ageing and improving —. (P) Desvignes.	36
Formation of sulphuretted hydrogen in fruit and grapes —. Osterwalder.	649
Grass sickness (ropiness) of —. Kayser and Mancau.	823
Improving — before fermentation. (P) Barbet.	947
Improving the quality of —. (P) Nilsson and Jonson.	1062, 1113r
Inversion of sucrose in —. Mathieu.	943
Occurrence of arsenic in —. Gibbs and James.	131
Persian —. Lecomte.	948
Rapidly clarifying, ageing, and maturing —. (P) Monti.	230
Sulphitation of — by sulphurous acid. (P) Laborde.	491
from vines attacked by mildew; Character of —. Manceau.	330
Wire; Heat treatment of steel —, especially for ropes.	539
Hermetically sealing — into glass. (P) Bastian and Calvert.	1156
Wires; Insulated —. (P) Rupley, and Gen. Electric Co.	28, 28
Wood; Action of bacteria on —. Malenkovic.	717
alcohol; Manufacture of —. (P) Chute.	824
Apparatus for distilling resinous —. (P) Wille.	171
Apparatus for extracting resins, &c., from —. (P) Weed.	12
Apparatus for extracting turpentine from —. (P) Pure White Turpentine Co., and Gardner.	82
Apparatus for forcing fluids into —. (P) Willner.	73
Apparatus for heating, steaming, drying, &c. —. (P) McWhirter.	1098
Apparatus for impregnating —. (P) Aitona.	848
Apparatus for impregnating or colouring —. (P) Farr and Kopetz.	1046
Bleaching action of light on dyed —. Schramm and Jung.	1092
Carbonising — by superheated steam. Ellström.	976
Cattle food from —. (P) Lehmann.	904
Charring —. (P) Müller.	921r
Colouring — to imitate old wood. (P) Kornmann.	817
Colouring and preserving —. (P) Mans et Ilac.	756
Composition for impregnating —. (P) Wolmar.	314
Distillation of —. (P) Jahn.	843
Distillation of — in the United States.	660
Distillation of — to produce wood spirit, acetic acid, acetone, and animal charcoal substitute. (P) Orilavacer Chem. Fabrik.	117
distilling apparatus: (P) James.	809
(P) Jewett.	805
distilling and preserving apparatus. (P) Davis and Richardson.	939
distilling retort: (P) Denny.	172
(P) Jackson, and Schofield's Sons Co.	1035
distilling; Retort furnace for —. (P) Brown, and Troy Chem. Manufg. Co.	1212
Drying — by preliminary treatment of the sap. (P) Soc. Guignard et Lestrande.	74
dyeing; Apparatus for —. (P) Schmidt.	1092
dyeing process. (P) Grünhut.	808
Effect of moisture on the strength of —. (U.S. Forest Service Report).	1148
Extracting oil of turpentine, &c., from —: (P) McKenzie.	1226
(P) Snyder.	1236
Extraction of rubber from —. (P) De la Corte.	584
Extraction of turpentine from —. (P) Snyder.	597
Extraction of turpentine and rosin from —. (P) Hale and Kurlatner.	895
fibre digester. (P) Handford, and Wood Distillates and Fibre Co.	88
fibresing apparatus. (P) Wood Distillates and Fibre Co.	32
Impregnation of —: (P) A.-G. f. Mechanische Holzbearbeitung.	375
(P) Poulsen.	999

Wood—cont.	
Impregnating and colouring —. (P) Mayerson.	846
Impregnating — to prevent putrefaction, rot, and fungus. (P) Hasselmann.	938
Improving the colour of impregnated or dyed —. (P) Hammerstein.	439
insects; Boring capabilities of a —. Hart.	458
Manufacture of artificial —. (P) Weibing.	439
oil; Oxidation of —. (P) Kramstein.	1087r
oils; Philippine —. Clovar.	899
Preparing — for polishing. (P) Bohne and Marx.	31
Preservation of —:	
(P) Card.	375
(P) Hoettger.	865r
(P) Logan.	1048
(P) Poulsen.	479
printing process. (P) Goodwin.	478
Producing dark colour on —. (P) Chem.-Techn. Laboratorium E. Bartels.	1218
Producing a liquid-tight joint between — and a dyeing or impregnating vessel. (P) Kron.	182
Production of paper pulp, terpene, and resinous substances from —. (P) Craighead and others.	494
pulp; Detection of mechanical —. Bergs.	918
pulp; Dyeing —. (P) Longley.	843
pulp production of Norway —. Krause.	37
pulp waste liquors; Sulphite —. Krause.	403
Reoudering — non-inflammable by means of non-hygroscopic compounds. (P) Rose.	288
resinous; Treatment of —. (P) Wood.	15
Rotary digester for sancharifying —. (P) Cie. Ind. des Alcool de l'Artache.	277
saprit; Continuous preparation of pure, concentrated —. (P) Farkas.	504
saprit; Production of — from wood and sawdust. (P) Orilavacer Chem. Fabrik.	117
still. (P) Coplovitch, and Standard Turpentine Manuf. Co.	367
supply of the world —. (P) Koeders.	1096
Distillation and oxidation of —. (P) Koeders.	529
Treating and colouring —. (P) Marino.	689
Treating — for paper manufacture. (P) Bergerhoff.	87
Treatment of —. (P) Mabery.	1046
Treatment of — for electrochemical apparatus. (P) Whitehead and Marino.	1088
Wool; Absorption of tin by — in tapestry-carpet yarn printing. Paterson.	585
Altering affinity for dyestuffs of fibres or fabrics containing —. (P) Hecke and Bell.	1218, 1218
Apparatus for cleaning, dyeing, &c. —: (P) Nicholas.	1090
(P) Wood.	1096
Bleaching — electrically. (P) Farns and Bomberg.	1217
bleaching process. Thierry-Mieg & Co.	425
carbonizing device. (P) Dupont.	686
Chlorination of —. Vignoo and Mollard.	1143
Cleaning — and recovering grease and solvent. (P) Quackenbush.	1218r
Detergent for scouring —. (P) Wohle.	969r
Discharges and half-discharges on — with potassium sulphite. Hellmann and Co., and Battgey.	434
Drying loose —. (P) Jahr.	1040r
Dyeing — with Aniline Black. (P) Bethmann.	783
Effect of chlorine on —. Vignoo and Mollard.	686
Extracting — with volatile solvents. (P) Lecomte.	754
Extraction of grease from —. (P) Burt and others.	451r, 881r, 881r
fat; Decomposition of —. (P) Lifschitz.	863r
goat hair, and camel hair; Sorting, whisking, washing, combing, and carding —. Statutory rule.	14
Increasing the fastness of Aniline Black dyes on —. (P) Bethmann.	317
lubricant soluble in water. (P) Risp and Basser.	310
Machine for treating loose — with liquids. (P) Mollard.	1090
Potash leaching apparatus for raw —. (P) Bergerhoff.	293
Printing — with mixtures containing phenol. Mueller.	889
Production of fast violet to blue shades on —. (P) Gelgy.	575r
rag; Carbonizing —. (P) Roberts.	961r
refuse; Fals from —. L.Sb.	985
rag; Dyeing and dressing —. Lamb.	14
scouring machines: (P) Jones.	478, 650r
(P) Kleinjung.	492
(P) Tillinghast.	493
Sterilising — to prevent anthrax. (P) Lockingill.	228r
washing apparatus: (P) Bastin.	15r
(P) Tetterton.	371r
Washing machine for — on bobbins. (P) Mamout.	381
at Cie.	619
washing soap in Natal.	619
Woolen fabrics; Production of multicoloured dye goods on —. (P) Becke.	372
goods; Detection of an in —. Paterson.	610
goods; Soap for finishing —. (P) Farns.	846
Grease; Washing and scouring machine for —. (P) Roussele.	811

JOURNAL OF THE Society of Chemical Industry.

No. 1.—Vol. XXV,

SUPPLEMENT.

January 15, 1906.

Journal and Patent Literature.

Class.	Page.	Class.	Page.
I.—General Plant, Apparatus and Machinery	7	XIII.—Pigments and Paints; Resins, Varnishes, &c.; India-Rubber, &c.	32
II.—Fuel, Gas, and Light	9	XIV.—Tanning; Leather; Glue, Size, Bone, and Horn; Ivory and Substitutes	33
III.—Destructive Distillation, Tar Products, Petroleum, and Mineral Waxes	12	XV.—Manures, &c.	34
IV.—Colouring Matters and Dyestuffs	13	XVI.—Sugar, Starch, Gum, &c.	34
V.—Preparing, Bleaching, Dyeing, Printing and Finishing Textiles, Yarns, and Fibres	14	XVII.—Brewing, Wines, Spirits, &c.	34
VI.—Colouring Wood, Paper, Leather, &c.	17	XVIII.—Foods; Sanitation; Water Purification; and Disinfectants	35
VII.—Acids, Alkalis, and Salts, and Non-Metallic Elements	18	XIX.—Paper, Pasteboard, Cellulose, Celluloid, &c.	35
VIII.—Glass, Pottery, and Enamels	20	XX.—Fine Chemicals, Alkaloids, Essences, and Extracts	35
IX.—Building Materials, Clays, Mortars, and Cements	21	XXI.—Photographic Materials and Processes	35
X.—Metallurgy	22	XXII.—Explosives, Matches, &c.	35
XI.—Electro-Chemistry and Electro-Metallurgy	27	XXIII.—Analytical Chemistry	35
XII.—Fatty Oils, Fats, Waxes, and Soap	30	XXIV.—Scientific and Technical Notes	35

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8s. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1s. each, to the Secretary of the Society.
French.—1 fr. 25 c. each, to Belin et Cie, 55, Rue des Francs-Bourgeois, Paris (2°).

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome, commencing on April 25th, 1906. All communications should be addressed to the General Secretary, Prof. Vittorio Villavecchia, Via Panisperna, 89, Rome.

Members are reminded that the subscription of 25s. for 1906, payable on January 1st, should be sent in good time to the Hon. Treasurer (Mr. Samuel Hall) in order to ensure continuity in the receipt of the Society's Journal. Any changes of address for the new List of Members now in course of preparation should reach the General Secretary not later than January 31st, 1906.

DECENNIAL INDEX, 1896-1905.

A Collective Index to the first fourteen volumes of the Journal (1892-1895), a volume of 550 pages, was published in 1899; a few copies of this are still left, price 10s. A second volume, embracing the period 1896-1905, is now in preparation, and will be ready for printing in 1906. It will contain both a subject matter and authors' names portion, and will be a volume of about 900 pages, uniform in size with the Journal. As the number of copies to be printed will depend on the number of applications from members, the Treasurer is prepared to receive subscriptions at the rate of 10s. each copy. A form of application for this purpose will shortly be issued.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Andreae, Dr. E. P., Crostalta (not Crostalba), Chamberlain Hill, S.E.

Anfilogoff, N. A.; Journals to Central Wharf, New, or Aykroyd, H. E.; communications to Ashdown, Ashdown Bridge, near Bradford.

Beaver, Chas. J., 1/o Cecil Road; Holme Lea, 1/o Cecil Road, Hale, Cheshire.

Bishop, J. T. F.; Journals to Chemical Club, Victoria Hotel, Manchester.

Bloxam, A. G.; communications to 105, Birkbeck Chambers, Holborn, W.C.

Boor, Leonard G., 1/o 39; 21, Mincing Lane, London, E.C.

Caro, Dr. Heinrich; Journals to C.8 N.9, Mannheim, Baden, Germany.

Clarke, Goddard; Journals to 80-84, Artillery Lane, London, E.

Dowhurst, Jno. A., 1/o Shipley; Borough, Halifax, Yorks.

Dickinson, A. J.; all communications to 57, Lewisham High Road, New Cross, S.E.

Douglas, London M., 1/o Baltic Wharf; Douglas, Warrington, Putney, S.W.

Doulton, H. L.; communications to Royal Doulton Pottery, Lambeth, S.E.

English, Frank H., 1/o Manor Park; 47, Shelley Avenue, East Ham, E.

Ethoridge, Arthur T.; all communications to Clifton House, Featherstone Road, Stanford, Essex.

Evans, Jas. R.; 1/o Troy; 19, High Street, Pottstown, Pa., U.S.A.; Chemist.

Fairhall, E. J.; 1/o London; c/o A. Beake, Roberts & Co., Ltd., 4 Rue Lamartine, Lille (Nord), France.

Fawsitt, Dr. Chas. E.; all communications to 9, Foremount Terrace, Glasgow.

Gall, Henry; 1/o Paris; 4, Rue Albert Joly, Versailles, France.

Gardner, Prof. Walter M.; Journals to Technical College, Bradford, Yorks.

Gasdar, J. J.; all communications to 5, Wroxham Mansions, Canfield Gardens, N.W.

Goulding, Sir W. Joshua, Bart.; 1/o Eden Quay; North Wall, Dublin.

Guthrie, Alan; 1/o Cawnpore; South End, Northallerton, Yorks.

Gyr, Dr. K. H.; 1/o Zürich; Zug, Switzerland.

Harden, Dr. Arthur; all communications to 2, Marlborough Road, Richmond, Surrey.

Hargreaves, Jas.; communications to May Villa, Pool House Lane, Widnes.

Harrison, G. Herbert; 1/o Middlewich; Hagley, Stourbridge.

Hatschek, Emil; 1/o New York; c/o Malto-Peptide Co., Ltd., Needham Market, Suffolk.

Hazen, C. R.; 1/o Collingwood; 33, Dartmoor Street, East Cleveland, Ohio, U.S.A.

Hollinshead, Peter; 1/o Middlewich; 10, The Hollow Way, Runcorn, Cheshire.

Jordan, Dr. D. S.; 1/o Edinburgh; Temora, Colinton, Midlothian, N.B.

King, Walter R.; 1/o Avalon; Holford Lodge, Trinity Avenue, Southend.

Kingzett, C. T.; 1/o Chislehurst; 1, Hornton Street, Kensington, W.; Journals as before.

Knudsen, Hans; 1/o Gillingham Street; 68, Victoria Street, Westminster, S.W.

Marsh, Wm.; Journals to Soho Works, Ancoats, Manchester.

Marx, Dr. Emil; Journals to 12, Gordon Street, Gordon Square, W.C.

Moore, Chas. W.; Journals to Glorietstrasse 66, Zürich IV., Switzerland.

Morson, Thos.; communications to 38, Elsworth Road, Primrose Hill, N.W.

Murrill, Dr. Paul I.; 1/o London; P.O. Drawer 986, Wilmington, Del., U.S.A.

Newall, F. S.; communications to Washington Station, B.S.O., Co. Durham.

Orr, Jno. B.; 1/o Widnes; Crossacres, Woolton, Liverpool.

Pakes, Dr. Walter C. C.; 1/o Box 1080; Box 4581, Johannesburg, South Africa.

Pearce, Richard; all communications to 1712, Sherman Avenue, Denver, Colo., U.S.A.

Reekie, J. A.; communications to Woodhouse, Hayfield, Derbyshire.

Render, Fred.; all communications to Underley House, Whitefield, Manchester.

Rink, Arnold; 1/o Butler Street; 14, Hamsell Street, London, E.C.

Royal-Dawson, H.; Journals to c/o Messrs Peyton and Son, Chemical Works, Lister Street, Birmingham.

Ruddock, F. G.; 1/o Egypt Street; Corporation Street, Warrington.

Schoeller, Dr. W. R.; 1/o Shoreditch; c/o D. C. Griffith and Co., Victoria Avenue, Bishopsgate Without, E.C.

Searle, Alfred B.; Journals to Cliftonville, Claremont, Sheffield.

Shearer, A.; 1/o 43; 5, Derby Road, Burton-on-Trent.

Shedden, Frank; 1/o Walsall; 25, Hareholme Lane, Clough Fold, Manchester.

Shonk, A.; 1/o Hendon; Alma, Merivale Road, Harrow.

Sindall, R. W.; Journals to Oxford Court, Cannon Street, London, E.C.

Sisson, G., Jun.; Journals to 13, Grey Street, Newcastle-on-Tyne.

Skurray, Thos.; communications to The Brewery, 40, Oak Street, Abingdon, Berks.

Smart, Bertram J.; 1/o Ennis Road; 35, Wrottesley Road, Plumstead, S.E.

Smith, F. Gurney; 1/o Blackburn; Dept. of Chemistry, Manitoba University, Winnipeg, Canada.

Sowerby, T. H.; communications to Canal Soap Works, Verney Road, Rotherhithe, S.E.

Van Marcke, J. C.; all communications to Technische Hochschule, Aachen, Germany.

Vernon, R. H.; 1/o London; c/o Westrumite Co. of America, 1117, Monadnock Building, Chicago, Ill., U.S.A.

Ward, G. J.; 1/o Nottingham; Hallam Fields, Ilkeston, Notts.

Whiffen, Thos. J.; 1/o Southfields; Carris House, West Hill, Putney, S.W.

Wilson, Leonard P.; 1/o Hanwell; Heath House, Wallasey Village, Cheshire.

Woolcott, G. H.; 1/o Montenotte; Lady's Well Brewery, Cork, Ireland.

Young, J. H.; communications to c/o Cassel Cyanide Co., Ltd., Shuna Street, Maryhill, Glasgow.

New Year's Honours List.

His Majesty has been pleased to confer the honour of Knighthood on Prof. Alex. Pedler, C.I.E., F.R.S., Director of Public Instruction, Calcutta.

Deaths.

Christy, Thos., The Manor House, Wallington, Surrey.

Crosskey, Alexander Nash, older son of Walter F. Crosskey, M.D., at Albion Street, Lewes. Jan. 7.

Ryland, Howard P., Moxhull Park, Erdington, Birmingham. Dec. 28.

Whichelo, Matthew A., at Woodleigh, Arundel Road, Eastbourne. Jan. 6.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

- [A.] 25,871. Messinger & Popper. Drying process and apparatus therefor.* Dec. 12.
- .. 26,040. Cole. Crucibles and furnaces. Dec. 14.
- .. 26,040A. Cole. Crucibles. Dec. 28.
- .. 26,065. Frache and Bouillon. Apparatus for the evaporation or concentration of liquids. [Ger. Appl., March 24, 1905.]* Dec. 14.
- .. 26,179. Humphrey. See under II.
- .. 26,409. Shaw. Apparatus for evaporating liquids. Dec. 19.
- .. 26,441. Watt. Kilns. Dec. 19.
- .. 26,705. Giron. Apparatus for charging vessels containing liquids with carbonic acid or other gas. [Fr. Appl., Jan. 14, 1905.]* Dec. 21.

- [A.] 26,801. Lovell. Machine for macerating and mixing substances. Dec. 22.
 „ 26,998. Clarke. *See under II.*
 „ 27,167. Kaufmann. Accumulators for gaseous bodies. Dec. 29.
 [C.S.] 25,204 and 25,204A (1904). Macquisten. Method and apparatus for separating solid particles from each other. Dec. 29.
 „ 27,618 (1904). De Kierzkowski-Steuart. Means for atomising liquid and gaseous fluids. Dec. 20.
 „ 27,875 (1904). Aktiebolaget Separator. Centrifugal separator for liquids. Dec. 30.
 „ 27,876 (1904). Aktiebolaget Separator. Centrifugal separators for liquids. Dec. 30.
 „ 29,178 (1904). Kestner and Liversedge. Centrifugal apparatus for purifying gases, applicable also for absorbing gas by liquids. Dec. 20.
 „ 29,329 (1904). Shaw. *See under XVI.*
 „ 29,512 (1904). Renshaw. Filtering apparatus. Dec. 29.
 „ 1646 (1905). Lennox. Spraying devices for evaporating liquids and for other purposes. Dec. 30.
 „ 5108 (1905). Crosfield and Markel. Separation of solids from liquids. Dec. 20.
 „ 5225 (1905). Yagn. Drying apparatus. Dec. 20.
 „ 6730 (1905). Voss and Stern. Producing heat and ignition by means of catalytic action. Dec. 30.
 „ 13,603 (1905). Jules Jean et Cie., and Raverat. Process for recovering vapours of volatile solvents. Dec. 20.

II.—FUEL, GAS, AND LIGHT.

- [A.] 25,926. Day and Wiesengrund. Suction gas producers. Dec. 13.
 „ 26,108. Harry. Steatite incandescent gas mantle. Dec. 15.
 „ 26,179. Humphrey. Apparatus for the treatment of gas, water and other liquids. Dec. 15.
 „ 26,189. Love. Inclined coal gas retorts.* Dec. 15.
 „ 26,262. Feld. *See under VII.*
 „ 26,496. Evans. Vapourising oil or the like for combustion. Dec. 19.
 „ 26,556. Campbell, Binnie and Reid (Smith). Apparatus for washing and separating coal and other minerals.* Dec. 20.
 „ 26,666. Dibdin and Woltercock. Process for the production of permanent heating and illuminating gas. Dec. 21.
 „ 26,763. Tangyes, Ltd., and Pitt. Producer gas plants. Dec. 22.
 „ 26,829. Fielding. Suction gas generators. Dec. 23.
 „ 26,847. Green and Mievile. Apparatus for producing gas from petrol for illuminating and heating purposes. Dec. 23.
 „ 26,855. Bourdos, Rothschild and Sutcliffe. Filaments of incandescent electric lamps. Dec. 23.
 „ 26,899. Browne. Treatment of spent oxide from gas purifiers for revivifying and rendering same fit for re-use.* Dec. 23.
 „ 26,900. Browne. Treatment of spent oxide from gas purifiers for revivifying and rendering same fit for re-use.* Dec. 23.
 „ 26,930. Bury and Brown. Carbonising coal. Dec. 23.
 „ 26,998. Clarke. Condensing apparatus suitable for the purification of coal and other gases. Dec. 27.
 „ 27,001. Hiby. Coke ovens. Dec. 27.
 „ 27,002. Bloxam (Lux). Manufacture of electric incandescence lamp filaments from tungsten or molybdenum or an alloy thereof. Dec. 27.
 27,184. Cox. Gas producing apparatus. Dec. 29.

- [C.S.] 24,372 (1904). Leistner. Liquid fuel burners. Dec. 20.
 „ 28,184 (1904). Kusel. Manufacture of light-emitting bodies for electric incandescent lamps. Dec. 29.
 „ 28,508 (1904). Neilson. *See under III.*
 „ 28,707 (1904). Wesselsky. Gas generator for the exploitation especially of dust coal. Dec. 29.
 „ 6434 (1905). Crosta and Morton. Gas producers. Dec. 20.
 „ 6794 (1905). Bell. Apparatus for the manufacture of gas. Dec. 29.
 „ 14,491. (1905). British Thomson-Houston Co., Ltd. (Gen. Electric Co.). Incandescent electric lamps and methods of making same. Dec. 30.
 „ 15,646 (1905). Brunok. *See under VII.*
 „ 19,995 (1905). Hutmachor. Production of carburetted generator or water gas. Dec. 20.
 „ 23,097 (1905). Siemens und Halske A.-G. Manufacture of incandescence bodies for electric light. Dec. 29.
 „ 24,136 (1905). Export-Gasglühlicht-Ges.m.b.H. Method of making incandescent bodies for incandescent gas lights. Dec. 30.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

- [A.] 26,917. Simpson. Decomposition of organic bodies. Dec. 23.
 [C.S.] 28,508. (1904). Neilson. Purification of and recovery of tar, &c., from blast-furnace, producer and like gases. Dec. 29.

IV.—COLOURING MATTERS AND DYESTUFFS.

- [A.] 26,383. Imray (Meister, Lucius und Brüning). Manufacture of *o*-oxymonosazo dyestuffs. Dec. 18.
 „ 26,495. Meister, Lucius und Brüning. Manufacture of a new vat dyestuff. [Ger. Appl., Jan. 30, 1905.]* Dec. 19.
 „ 27,000. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of an indoponol. Dec. 27.
 [C.S.] 28,547 (1904). Lichtenstein. Products applicable as colouring matters and for other industrial purposes. Dec. 30.
 „ 8908 (1905). Ransford (Cassella und Co.). Manufacture of new sulpho acids and dyestuffs therefrom. Dec. 29.
 „ 9325 (1905). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of a new *p*-amidophenylethersulphonic acid and a colouring matter therefrom. Dec. 29.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

- [A.] 25,693. Feilmann. *See under XIII.*
 „ 25,752. Lake (Soc. Anon. Coop. per la Stagionatura e l'Assaggio Delle Sete ed Affini). Treatment of silk.* Dec. 11.
 „ 25,816. Young and Hardman. Bleaching vegetable fibres in the raw or manufactured state. Dec. 12.
 „ 25,874. Koehler. Cop tubes. [U.S. Appl., Aug. 25, 1905.]* Dec. 12.
 „ 26,173. Meister, Lucius und Brüning. Manufacture of a hydrophilic preparation. [Ger. Appl., Dec. 26, 1904.]* Dec. 15.
 „ 26,381. Johnson (Badische Anilin und Soda Fabrik). Pastes for the discharge of dyed textile fabrics.* Dec. 18.

- [A.] 26,762. Mather and Platt, Ltd. (Marin). Apparatus for dyeing, washing and finishing fabrics and the like. Dec. 22.
- " 26,962. Bethmann. Process for dyeing wool or other animal fibres with Aniline Black.* Dec. 27.
- " 27,054. Arrowsmith. Machinery for washing, scouring, dyeing, drying, and otherwise treating textile piece goods. Dec. 28.
- " 27,222. Dreaper. Manufacture of artificial silk and the like filaments. Dec. 30.
- [C.S.] 28,712 (1904). Tompkins and Crombie. Manufacture of fibres or threads from cellulose solutions. Dec. 30.
- " 29,272 (1904). Haddan (Bailloncourt). Machines for the preparation of textile vegetable fibres. Dec. 30.
- " 300 (1905). Waters. Dyeing machines. Dec. 29.
- " 1120 (1905). Moore and Moore. Apparatus for washing and drying fabrics, fibrous substances, &c. Dec. 29.
- " 6750 (1905).*Fulton. Machines for treating or finishing fabrics. Dec. 29.

VI.—COLOURING WOOD, PAPER, LEATHER, ETC.

- [C.S.] 27,870 (1904). Imray (Meister, Lucius and Brüning). Manufacture of irregularly coloured paper. Dec. 20.
- " 9119 (1905). Boulton (Hurwitz and Schürmann). Gilding of paper and other materials. Dec. 20.
- " 17,163 (1905). Tittel. Apparatus for applying colouring matter in paper making machines for the manufacture of coloured and marbled papers. Dec. 20.

VII.—ACIDS, ALKALIS, AND SALTS.

- [A.] 26,205. Lewis. Treatment of graphite for the removal of siliceous or other impurities therefrom. Dec. 16.
- " 26,262. Feld. Treatment of gases for the extraction of ammonia therefrom. Dec. 16.
- " 26,380. Johnson (Badische Anilin und Soda Fabrik). Manufacture of stable dry hydrosulphites. Dec. 18.
- " 26,435. Soc. l'Air Liquide. Liquefying atmospheric air in several portions differing in composition. [Fr. Appl., March 30, 1905.]* Dec. 19.
- " 26,489. Cooper. Manufacture of sulphuric acid. Dec. 19.
- " 26,661. Brown. Method of utilising the arsenical product precipitated in the purification of hydrochloric, sulphuric and like acids. Dec. 21.
- " 26,728. Pawlikowski. Production of endothermic chemical compounds.* Dec. 21.
- " 26,788. Potter. Manufacture of silicon monoxide. [U.S. Appl., Dec. 30, 1904.]* Dec. 22.
- " 26,803. Kaiser. Process for producing ammonia. [Ger. Appl., Dec. 24, 1904.]* Dec. 22.
- " 27,009. Johnson (Badische Anilin und Soda Fabrik). See under XI.
- " 27,014. Rice and Johns. Pyrites burners or kilns. Dec. 27.
- [C.S.] 27,907 (1904). Blackmore. Process of making sulphur trioxide and other compounds exothermic on formation. Dec. 30.
- " 28,433 (1904). De Stucklé. Manufacture of caustic alkalis or analogous hydrates. Dec. 29.
- " 29,283 (1904). Bloxam (Administration der Minen von Buchweiler A.G.). Manufacture of sodium ferrocyanide. Dec. 20.
- " 29,302 (1904). Walker (Ray). Apparatus for evaporating brine. Dec. 30.

- [C.S.] 9443 (1905). Cleam. Treatment of phosphates and production of chlorine and of citrate soluble phosphate. Dec. 20.
- " 15,646 (1905). Brunck. Extraction of ammonia from distillation gases. Dec. 20.
- " 21,347 (1905). Bloxam (Gebr. Siemens und Co.). Manufacture of forms of silicon carbide. Dec. 30.
- " 22,238 (1905). Wedge. Preparing iron pyrites for desulphurisation. Dec. 30.

VIII.—GLASS, POTTERY, AND ENAMELS.

- [A.] 26,469. Moore. Furnaces for glass manufacture, &c. Dec. 19.
- " 26,642. MacHutcheon and MacHutcheon. Decorating porcelain and vitreous enamelled ware.* Dec. 21.
- " 26,893. Thompson. Treatment and utilisation of the waste sand (burgy) from glass works. Dec. 23.
- [C.S.] 28,078 (1904). Stanley. Apparatus for burning the colours on tiles, glass, porcelain and ceramic ware. Dec. 19.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

- [A.] 26,007. South. Yorkstone cement. Dec. 14.
- " 26,539. Smith and Atherton. Asphalt compositions for road making and the like. Dec. 20.
- " 26,993. Hoettger. Preservation of wood. [Fr. Appl., March 22, 1905.]* Dec. 27.
- " 27,082. Angelis. Heat resisting composition. Dec. 28.
- [C.S.] 27,308 (1904). Ward. Tar paving. Dec. 20.
- " 27,309 (1904). Ward. Manufacture of tar paving. Dec. 20.
- " 28,349 (1904). Brador. Heat insulating coverings. Dec. 30.
- " 5763 (1905). Assoc. Portland Cement Manufacturers (1900), Ltd., and Brooks. Manufacture of cement. Dec. 30.
- " 5797 (1905). Rawlings. Preparing lithographic stones. Dec. 29.
- " 14,288 (1905). Jacobs. Building materials. Dec. 29.

X.—METALLURGY.

- [A.] 25,748. Simpkin and Ballantine. Magnetic separator. Dec. 11.
- " 25,845. Gillies. Apparatus for winning zinc and other sulphides from their ores. Dec. 12.
- " 25,941. Allison (Byrde). Percolation vats for treating ores. Dec. 13.
- " 25,976. Johnson (Saponia-Werke F. Boehm). See under XIII.
- " 26,076. Babé and Louvrier. Metallurgical furnaces. [Ital. Appl., Dec. 14, 1904.]* Dec. 14.
- " 26,170. Goldschmid. Process for balling together pulverulent or dusty ores. [Ger. Appl., Jan. 12, 1905.]* Dec. 15.
- " 26,263. Frodingham Iron and Steel Co., Ltd., and Mannaberg. Blast furnaces.* Dec. 16.
- " 26,277. Heberlein. Treatment of metalliferous compounds preparatory to smelting. Dec. 16.
- " 26,471. Angel. Treatment and reduction of complex sulphide ores. Dec. 19.
- " 26,472. Angel. Furnaces for treating sulphides or other ores. Dec. 19.
- " 26,529. Cowper-Coles. Zinc alloys. Dec. 20.
- " 26,530. Cowper-Coles. Manufacture of alloys. Dec. 20.

- [A.] 26,534. Patchin and Rumbold. Method of obtaining lead and silver from ores or residues containing lead as sulphate or in a form capable of conversion into sulphate, and the silver as chloride. Dec. 20.
- „ 26,556. Campbell, Binnie and Reid. *See under* II.
- „ 26,577. Frith and Grist. Treatment of metals such as steel. Dec. 20.
- „ 26,579. Frith and Grist. Treatment of metals such as steel and steel alloys. Dec. 20.
- „ 26,580. Frith and Grist. Treatment of metals such as steel and steel alloys. Dec. 20.
- „ 26,711. Sulman, Picard and Ballot. Separation of minerals. Dec. 21.
- „ 26,712. Sulman, Picard and Ballot. Ore concentration. Dec. 21.
- „ 26,790. Baker. Treatment of complex sulphide ores. Dec. 22.
- „ 26,813. Ashcroft. *See under* XI.
- „ 26,980. Heskott. Process and apparatus for obtaining metals from their sulphides. Dec. 27.
- „ 27,023. Hemme. Brazing, and fluxes employed therein. Dec. 27.
- „ 27,066. Cook. Metallurgical processes. Dec. 28.
- „ 27,118. Fraser. Metallurgical process. Dec. 29.
- „ 27,218. Blackman (Emett). Hardening cast iron and the like. Dec. 30.
- [C.S.] 27,977 (1904). James. Extraction of precious metals from their ores. Dec. 30.
- „ 28,570 (1904). Defays. Manufacture of steel. Dec. 30.
- „ 1697 (1905). Wynne. Concentration of ores or other substances of different specific gravities. Dec. 29.
- „ 2286 (1905). Rollaston. Treatment of auriferous, refractory or base ores. Dec. 30.
- „ 2337 (1905). De Souza. Extraction of aluminium compounds for use in the manufacture of aluminium or aluminium alloys. Dec. 20.
- „ 16,232 (1905), 16,233 (1905), and 16,234 (1905). Wedge. Preparing iron oxide for treatment in furnaces. Dec. 20.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

- [A.] 2004A. Bastian and Calvert. Electrode material for vapour electric apparatus. Dec. 30.
- „ 26,662. Braun. Electrical batteries. Dec. 21.
- „ 26,813. Ashcroft. Electrolysis of metallic compounds or ores. Dec. 22.
- „ 26,876. Boulton (Stebbins). Secondary batteries.* Dec. 23.
- „ 26,902. Cowper-Coles. Electrolytic production of metallic sheets, wire, tubes, strip or the like. Dec. 23.
- „ 26,903. Cowper-Coles. Anodes. Dec. 23.
- „ 27,009. Johnson (Badische Anilin und Soda Fabrik). Electrolytic production of chromic acid and apparatus therefor. Dec. 27.
- „ 27,159. Danville. Accumulators. Dec. 29.
- [C.S.] 25,839 (1904). Thorp. * Electrolysing apparatus. Dec. 30.
- „ 27,986 (1904). N.S. Electric Storage Co., Ltd., and Niblett. Storage batteries. Dec. 29.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

- [A.] 26,119. Pochin and Richardson. Manufacture of soap powders or detergents. Dec. 15.
- 27,264. Kleyer. Manufacture of lubricating and anti-corrosive oils. [Ger. Appl., Jan. 4, 1905.]* Dec. 30.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A.)—PIGMENTS, PAINTS.

- [A.] 25,693. Feilmann. Products for use in dyeing and printing, and as pigments. Dec. 11.
- „ 25,859. Fireman. Manufacture of printing ink pigments.* Dec. 12.
- „ 27,036. Mills. Converting lead sulphate into a basic pigment and preparing paint therefrom. Dec. 28.
- „ 27,252. Imray (Meister, Lucius und Brünig). Manufacture of colour lakes. Dec. 30.

(B.)—RESINS, VARNISHES.

- [A.] 25,976. Johnson (Saponia-Werke F. Boehm). Material for cleaning and protecting metal. Dec. 13.
- „ 26,176. Bosch. Process for treating rosin and rosin oils.* Dec. 15.

(C.)—INDIA-RUBBER.

- [A.] 26,247. Finney. Method of treating india-rubber for commercial purposes. Dec. 16.
- [C.S.] 7694 (1905). Morisse. Treatment of the lactiferous juices of caoutchouc, gutta percha, balata and the like. Dec. 20.

XIV.—TANNING, LEATHER, GLUE, SIZE, Etc.

DR. G. H. BAILEY IN THE CHAIR.

CHIMNEY DRAUGHTING AND CONNECTING FLUES IN CHEMICAL WORKS.

BY HERBERT PORTER, F.I.C.

Much work has been done with reference to the volume and flow of gases or air in pipes, and many men of note have given the subject their close attention. Two hundred years ago Pitot studied this subject, and since then many others, coming down to the present day, such workers as Unwin, Threlfall, Fletcher, Lunge, Swan, Heenan, Gilbert, &c., &c., have all contributed to the subject mainly from a mathematical point of view. I do not intend to touch upon that subject, but I venture to think that the study of the mode of motion of gases in vessels, flues, or chimneys has not been made the subject of such close study as that of volume and velocity. By many, my experiments on the movement of gases in vitriol chambers will still be remembered, and I am proud to say the paper I read before this Society on that subject has created considerable interest both in this country and in America, and that the practical working on the lines laid down has proved the theory to be to a great extent correct. Being encouraged thus far, it is with the hope of throwing some further light on this question that the following paper was prepared.

The question of chimney draughting and connecting flues in works of all kinds, including chemical works, does not always receive the attention it should do, especially in old works where many changes in management and methods of working have taken place, or where the addition of fresh plant, if not new processes, has from time to time taken place. In a chemical works the chimney is the main spring which drives the whole machinery, and unless this means of promoting power be in proper proportion to the work to be done, or the connecting flues to the chimney be properly constructed, there will be trouble, loss in time and fuel, low level and local escapes, to say nothing of alterations, repairs, and experiments which otherwise would be unnecessary. In many otherwise well appointed works, or well constructed plant, troubles and difficulties arise from insufficient attention to the construction of flues in relation to the existing chimney draught. Also there is a note of warning needed to many on the question of employing electrical power in place of steam engines, or employing gas engines. These agents for power may pay for the particular purpose they are employed for, but in adopting such means there must be a corresponding reduction in the amount of steam generated and that means also a reduction of heat and reduction of motive power in the chimney.

Many processes carried on in a chemical works can be worked by the aid of artificial draught, such as fans, which are daily coming more into use, where the gases to be draughted are such as can be dealt with by a fan. On the other hand, there are gases which are almost impossible to deal with in that way and the manufacturer must look to

the chimney draught for his motive power. The first point for consideration, after it has been decided to extend a plant, or put down an additional process, is the velocity and temperature of the chimney gases, and the velocity and capacity of the main flue to which such additional plant is to be attached. If the process to be added will contribute heat there will probably be an increase in velocity, and an increase in velocity means greater friction, which is another factor to be taken into consideration. Also there may be loss of power or draught due to the sudden enlargement of a flue, or to sharp bends, or to the entrance of other flues at right angles causing an eddy or whirlpool. Or, again, a new flue may be connected with the main flue contributing a large volume of cold gases, which will reduce the speed and increase the volume beyond the capacity of the flues. As regards steam boilers and furnaces, an insufficiency of draught in a chimney means loss of heat, incomplete combustion, and consequently loss in fuel, while, on the other hand, too much draught means also loss of heat due to excess of air drawn through the fires, and also increased consumption of coal. Having these points to bear in mind, it may be said that any speed over 40 ft. per second is excessive in a works chimney. At many works with which I am acquainted, the chimneys taking gases from various chemical processes as well as the boiler fire gases or furnace gases, very seldom exceed 7 to 8 ft. per second. Taking seven of the principal works where many processes are connected to one chimney, the average speed is 4.73 ft. per second, and these chimneys are all somewhat about the same height. The rule for calculating the power of a chimney is that the power varies as the square root of the height, but the temperature of the gases in the chimney also have an important relation to the power or speed. A tall chimney with a low temperature would be less powerful than a medium chimney draughting gas of the same temperature, because the question of friction and loss in temperature has to be considered.

It is generally assumed that inside all chimneys of whatever dimensions, there is a lining of gases for a thickness of about 2 in., that is practically stationary, that is to say, it has no upward velocity of any appreciable degree. It is often said that necessity is the mother of invention, but a study of nature and natural laws will often show that modern invention has been anticipated from the earliest times, and such natural phenomena will still be observed even under unnatural conditions. The principle of the ball bearings of a bicycle is understood by most people, and this same principle applies to the smoke ascending a chimney, acting in a line with the shaft instead of round its circumference as in the case of the bicycle. The lining or stationary gas at the sides of the chimney acts in the same way as the ball bearing, by revolving tubes or discs of gas, probably tubes, which allow the main shaft or core of gas to rapidly pass up the chimney, thus reducing the friction. As a further illustration of this ball-bearing movement may be instanced the hull of a ship at the water line, where the movement of the water at the sides of the vessel is very much the same as the movement of the gases at the sides of the chimney, making due allowance for the difference between gas and water. The hull of the ship represents the body of moving gases passing up the chimney, the water being the chimney and the sails of the vessel the motive power. This action can be seen in narrow canals, when a canal boat is moving along.

Again in the case of a stream of water running between two banks, most people will have noticed the vortex action at the bank side, wherever the least obstruction or unevenness exists. Nature in this way reduces friction, and if it were not so, the movement of the gases in the chimney would be difficult, likewise the vessel in the water, or the water in the stream.

This ball-bearing movement can be seen, under certain conditions, in the exit flue from a set of vitriol chambers, by looking into the flue through a $\frac{3}{4}$ in. or 1 in. hole at an angle from its centre, especially if there be a small glass window in the opposite side of the flue, a little above the hole of observation. It is well known that there is little or no motion indicated by the anemometer when the tubes are placed just inside the chimney wall,

Fig B.

as possible. In Fig. F, *x*, *y*, *z*, show these pipes, *x* and *y* being examples of wrong construction; in Fig. F *z* shows a small connection as it should be, the side of the pipe projecting into the main flue, and Fig. E shows the junction of two large flues of about the same size, in which will be noticed a partition wall or midfeather.

It is absolutely wrong to connect a flue into the top of the main flue, for at that point the velocity of the main flue gases is greatest, and this will prevent the gases taken from the connection from entering, at least in the proportion they are required to do. (Fig. C.)

Flues draughting cold gases to a hot flue must be of a capacity fully equal to that enjoined by rules to be found in many works on the subject, and such gases should be conducted into the main flue at the side and above the centre line or on it, level with the line of greatest speed, with a connection such as shown in Fig. D.

One most important point should never be lost sight of: never attempt, as is sometimes done, to make cold gases go uphill if you value your chimney draught, or wish to avoid local escape, and do not try to make hot gases go down hill, for the same results will face you. When I say hot gases going downhill I do not mean fire gases in boiler flues, or furnace gases in a *plus* pressure furnace, but the gases from various processes after they have left their point of generation, and are on their way to the main flue, when they are losing their heat or coming in contact with frictional surface.

I hope in the near future to bring forward another paper that will deal more fully with the subject as regards the movement and speed of the gases in chimneys and flues.

DISCUSSION.

Mr. W. H. COLLEMAN could confirm Mr. Porter's statement with regard to the splitting action where a flue had been put in above the ground level. In a chimney which had been treated in that way a considerable crack had developed. He thought Mr. Porter's suggestion of a flat stone above the arch would overcome a difficulty which had not been met before. He also agreed with

the author's remarks as to the eddying action and the method of connecting flues.

Mr. WM. THOMSON asked whether it was quite clear that the draught of a chimney was proportional to the square root of its height? The experiment, to show that the velocity of the draught in one flue was largely dependent on the angle at which it joined the main flue, was very interesting. With regard to the worst results being obtained when they joined at right angles, he would like to know how this worked out on a Fletcher's anemometer, where a tube, the opening of which was placed at right angles to the draught, was supposed to produce a partial vacuum in that tube, proportional to the pressure produced in another, the opening in which was turned to face the draught.

Mr. THORP explained that the reason, why the velocity of gases in a chimney varied as the root of the height only, was that the energy required varied as the square of the velocity, whilst the energy only varied directly as the height. He also gave an explanation of the means adopted to overcome a difficulty in connection with a new type of meter, which bore out Mr. Porter's observations as to the nature of the motion of gases near the walls of a conduit.

Dr. F. H. BOWMAN had had considerable experience in the construction of chimneys, and he thought it was a great mistake to taper them. They ought to be built wider at the top than the bottom in order that the gases might have a clear outlet. In one case he had fixed baffle plates in boiler flues, and this improved the draught very considerably. It was a great mistake to make the flues at right angles instead of with bends.

Dr. J. GROSSMANN asked in what way Mr. Porter determined the 2 ins. lining on the side of the chimney?

Mr. LEASK said that with regard to the flow of gas in the chimneys he agreed with Mr. Porter. There was a layer between the wall of the chimney and the body of the moving gases. The thickness of the layer was about 2 ins. and was caused by the retarding action of the walls of the chimney. He thought this layer had some motion, but did not think it could be treated mathematically. He agreed with Mr. Thorp as to the velocity of the gases in the chimney, i.e., that they were directly proportional to the square root of the height of the chimney, the mean temperature being constant. With regard to the junction of flues, he always constructed them at an acute angle in the direction of the flow, in the manner indicated by Mr. Porter, and he thought that the reason why flues were often brought in at right angles was to get over the difficulties of construction, which were considerable with acute angles when the gases passing through the flues were of a high temperature. To get over this difficulty he had always constructed the flues at the junction with a flat top.

Mr. HERBERT PORTER, in reply, said Mr. Thorp had already replied to Mr. Thomson as to the square root question, but in his (Mr. Porter's) opinion there was the question of friction and loss of temperature, for which some allowance must be made. A high chimney with a very low temperature would not be so effective as a medium chimney at the same temperature. Mr. Thomson also mentioned right angle flues and quoted Petot's experiments. Prof. Unwin had shown that with a larger orifice a correct suction was not obtained. In the "Proceedings of the Institution of Mechanical Engineers," in April, 1904, Mr. Threlfall read a paper on that subject which was well worth perusal. With regard to anemometer tubes, he fully realised the advantage of having a flanged pipe for the suction, which prevented the eddying described by Prof. Unwin. The lining undoubtedly had an upward motion, but what proportion that held to the speed of the gases generally he was not prepared to say, but probably it would be very low. He was also glad to hear Mr. Leask's experience that flat top flues increased the velocity—that there would be more lubricating action, which would give a better result. Dr. Bowman confirmed his method of connecting flues and the advantage of inserting baffle plates. In reply to Dr. Grossmann, the action referred to could be seen in

the exit from vitriol chambers by looking through a three-quarter inch hole in the flue at an angle from its centre. The anemometer showed no velocity just inside the chimney, only a slight oscillation on the surface of the ether. He was glad to hear from Mr. Thorp that by making a lip at the end of the tube the globules were arrested at the sides and accurate delivery was the result. By this means the friction was reduced to a minimum at the point of discharge. As to the width of chimney necessary to obtain the maximum of 2 ins. of eddying matter inside, the gas lining varied with the size of the chimney. It was generally admitted that 2 ins. was the usual amount in most chimneys of average size.

New England Section.

Meeting held at Boston, on Friday, December 1st, 1905.

MR. HENRY HOWARD IN THE CHAIR.

THE CONTACT PROCESS FOR MANUFACTURING SULPHURIC ACID OF THE VEREIN CHEMISCHER FABRIKEN IN MANNHEIM.

BY WM. WILKE.

This process is based on the following fundamental principles:

1st. To use the heat of the ordinary roasting process for carrying on the catalytic action of the oxide of iron upon the sulphurous acid.

2nd. The purification of the burner gases is a dry process. In all other processes the gases are washed and have to be dried again.

3rd. The conversion or catalytic oxidation of that part of the sulphurous acid which passed through the iron contact, but had not been converted, is brought about by means of platinum and reheated to the proper temperature by means of the waste heat of the burner gases.

4th. The whole process is carried on by moving the gases by means of exhausters only.

The roast gases leave the kilns at a temperature of about 700° C. This is the proper temperature necessary in the iron oxide to produce the conversion or catalytic action to transform the sulphurous acid into sulphuric anhydride. The iron oxide, at the above mentioned temperature, forms iron arsenate, with the arsenious acid which is contained in the roast gases. If roast gases are taken at the temperature of the furnace through the oxide of iron, a large proportion of the sulphurous acid (50—60 per cent.), is converted into sulphuric anhydride while the arsenic contained in these roast gases combines with the oxide of iron.

Water contained in the gases to be converted reduces the catalytic property of the iron oxide; it is, therefore, necessary to produce the roast gases with dried air. The drying of the air necessary for the process is accomplished with sulphuric acid which is produced in the process.

The roast gases are produced in a furnace which is protected with an air-tight iron shell, against any entrance of moist atmospheric air. The air necessary for the roasting process passes through towers which are scrubbed with sulphuric acid and is then conducted through air-tight pipes entering the furnace or kilns below the grate bars. The dry and hot roast gases so obtained are conducted to a shaft which is attached to the furnace and filled with oxide of iron (pyrites cinders). In this shaft part of the conversion takes place, that is, part of the sulphurous acid is converted into sulphuric anhydride, while at the same time the arsenic obtained in the roast gases is retained.

The roast gases therefore are subjected to a dry purification, and are considerably reduced in their contents of sulphurous acid. After the sulphuric anhydride which is

formed in this first part of the process has been absorbed, the rest of the sulphurous acid contained in the gases can be converted into sulphuric anhydride by means of a very small amount of platinum. To do this, it is necessary to remove any small quantities of sulphuric acid (monohydrate) which have not been absorbed. This is accomplished by passing the gases through layers of porous material which is not affected by sulphuric acid. The main part of the sulphuric acid which is carried over mechanically is eliminated or retained in this way. The purified gases are now allowed to pass through layers of granulated basic blast-furnace slag.

The gases which have passed through the iron contact mass contain sufficient heat to reheat the filtered gases to the temperature necessary for catalytic action in the platinum contact.

It would be possible to utilise this heat by giving it off to the filtered gases. But the sulphuric acid (monohydrate) must be carried along in the form of vapour. The heat, therefore, must not be reduced too much to keep the monohydrate in a gaseous state. The heat given off in the heater located over the iron contact is not sufficient to raise the filtered gases to the temperature necessary to carry on catalytic action in the platinum contact. It is, therefore, necessary to have a small coal fire to raise these gases to their proper temperature.

The platinum contact apparatus must be built in such a way that it does not offer much resistance to the passage of the gases, in order to move them with an ordinary exhauster. This is accomplished by using a number of platinised asbestos nets, the meshes of which are such that the resistance in the whole apparatus does not represent more than the pressure of a column of water about 30 mm. high. In constructing the platinum contact apparatus in this way, it is possible to exchange a single element during the process in the course of a few minutes without interruption. In this process, it is possible to have a conversion of the roast gases up to 95 per cent.

The first plant in the United States was erected in 1903, in the works of the Schoellkopf, Hartford and Hanna Co., in the city of Buffalo, N.Y. This plant consisted then of one unit with a capacity of about 1600 tons of sulphuric acid or its equivalent. The original plant has since been enlarged to four times its original capacity. Besides this plant, four other firms have adopted this process, and there are now in use twenty-two units with a capacity of about 35,000 tons, and in the course of construction, ten more units with a capacity of 16,000 tons. This is a total capacity of over 50,000 tons per year. This has been accomplished in a little over two years since the process has first been introduced here.

This process does not require complicated or delicate pieces of apparatus, a staff of scientific men, nor any special apparatus for the purification of the roast gases, as this is done in the furnace itself. The amount of fuel consumed and motive power required is smaller than in any other known process, and the plant can be built up gradually on account of the units being small and being easily arranged in groups. The cost of repairs is very low.

Meeting held at Chemists' Club, on Friday, November 24th, 1905.

DR. RUSSELL W. MOORE IN THE CHAIR.

THE EXISTENCE OF BROMOUS ACID (HBrO₂).

BY A. H. RICHARDS.

The following experiments were conducted in the laboratory of the Telluride Mill, at Colorado Springs, Colo. :—

The effect of adding a cold aqueous solution of silver

nitrate, in excess, to bromine water is the formation of hypobromous acid, silver bromide and nitric acid—

The effect of adding liquid bromine, in excess, to a concentrated solution of silver nitrate, gives a different reaction, as is shown by the following experiments:—To about two litres of an almost saturated solution of silver nitrate, liquid bromine was added in large excess. After stirring well and filtering, 18 equal portions of solutions were taken and put into flasks, which were numbered from 1 to 18. From portions numbered 1, 2, 3 and 4 the bromine was blown out by means of an air blast. From portions numbered 5, 6, 7 and 8 the bromine was removed by means of carbon bisulphide. Numbers 9 to 18 were set aside for other tests.

Portions 1, 2, 5 and 6 were made alkaline with sodium hydroxide, potassium iodide added, and then the solution made slightly acid with sulphuric acid. The iodine (which was liberated by the oxygen from the acid bromine compound) was titrated with standard sodium thiosulphate. The following amount of oxygen was found to be present:—

No. 1=0.1495	grms. of oxygen.
" 2=0.1497	" " "
" 5=0.1504	" " "
" 6=0.1503	" " "

Average = 0.14975 " " "

Portions numbered 3, 4, 7 and 8 were reduced by means of sulphurous acid, the excess of sulphurous acid being oxidised with potassium permanganate, and, after making the solution alkaline with sodium bicarbonate, the bromide was titrated with N/10 silver nitrate solution and chromate indicator. The following results were obtained:—

No. 3=0.3745	grms. of bromine.
" 4=0.3742	" " "
" 7=0.3747	" " "
" 8=0.3746	" " "

Average = 0.3745 " " "

From these eight tests the proportion between the oxygen and the bromine in the acid bromine compound was established as O : Br :: 0.14975 : 0.3745. This shows that the acid bromine compound contains two atoms of oxygen to one of bromine, and is presumably bromous acid (HBrO_2).

To further establish the existence of bromous acid in the solution, portions of the solution numbering 9, 10, 11 and 12 were used. These experiments were conducted on the supposition that bromous acid would react with hydrobromic acid in a manner analogous to the reaction between bromic acid and hydrobromic acid, and between hypobromous acid and hydrobromic acid, the reaction being $3\text{HBr} + \text{HBrO}_2 = 2\text{H}_2\text{O} + 2\text{Br}_2$.

After removing the free bromine from the four portions by means of an air blast, the solutions were made alkaline with sodium hydroxide, and an excess of sodium bromide was added. The solution was now transferred into a three-necked Woulff bottle. Dilute sulphuric acid was added through a stopcock funnel and the bromine, liberated by the action of hydrobromic acid on the supposed bromous acid, was blown into a solution of potassium iodide. The iodine liberated was titrated with standard sodium thiosulphate. The bromine found to have been liberated from the four tests were as follows:—

No. 9=1.496	grms. bromine.
" 10=1.499	" " "
" 11=1.497	" " "
" 12=1.498	" " "

Average = 1.4975 " " "

As was shown in tests numbering 3, 4, 7 and 8, the bromine existing in the solution was 0.3745 gm. Subtracting 0.3745 gm. from 1.4975 gm. leaves 1.1230 gm. of bromine, which is the bromine liberated from the hydrobromic acid. Dividing 1.123 by 0.3745 gives

the quotient of 2.9987. This gives the ratio between the bromine liberated from the supposed bromous acid and the bromine liberated from the hydrobromic acid as 1 to 2.9987, compared with the ratio 1 : 3 found from the equation $3\text{HBr} + \text{HBrO}_2 = 2\text{Br}_2 + \text{H}_2\text{O}$.

After removing free bromine from solutions numbering 13, 14, 15 and 16 and making alkaline with sodium hydroxide, the theoretical amount of sodium bromide was added, the solution made slightly acid as in previous tests (9, 10, 11 and 12), and the bromine blown into a solution of potassium iodide. The bromine liberated was found to be:—

No. 13=1.495	grm. bromine.
" 14=1.497	" " "
" 15=1.497	" " "
" 16=1.496	" " "

Average = 1.49625 " " "

The solution, to which the sodium bromide had been added, and from which the bromine had been liberated, was tested for excess bromide and only a faint trace could be detected in numbers 13 and 16. This, together with the bromine found to have been liberated in tests 9, 10, 11, 12, 13, 14, 15 and 16, shewed that bromous acid probably did exist in the solution, and that the reaction is $3\text{HBr} + \text{HBrO}_2 = 2\text{H}_2\text{O} + 2\text{Br}_2$.

From the results which are given above, it must be concluded that the addition of liquid bromine, in excess, to a concentrated solution of silver nitrate, a bromine acid is formed which contains two atoms of oxygen to one atom of bromine. Whether this was bromous acid or a mixture of one part of hypobromous acid and one part of bromic acid was next investigated. If it were proven that hypobromous acid did not exist in the solution, then it could not be a mixture of one part of bromic acid and one part of hypobromous acid. To satisfy this point, the following facts were made use of, viz.:—Silver nitrate added to solutions of hypobromites with bromides, precipitates the bromide at first, leaving hypobromites in solution, while the soluble silver hypobromite decomposes with the precipitation of bromide and formation of bromate of silver. The bromate of silver gradually changing to the bromide— $3\text{AgBrO} = 2\text{AgBr} + \text{AgBrO}_3$.

Portions numbering 17 and 18 were prepared by removing the free bromine and then making just alkaline with sodium hydroxide, a small crystal of sodium bromide added. Silver nitrate was added in excess, and the solution rapidly filtered. The solution was allowed to stand for some time and no more precipitation of AgBr took place, showing that no silver hypobromite had been formed, and consequently no sodium hypobromite present. If no sodium hypobromite was present, after making the solution alkaline with sodium hydroxide, it is evident that no hypobromous acid was present in the acid solution and the bromine acid was not a mixture of one part of bromic acid and one part of hypobromous acid.

From the above experiments, the author's conclusions are, that bromous acid does exist and can be formed by adding liquid bromine, in excess, to a concentrated solution of silver nitrate. The first formation is probably hypobromous acid, which is oxidised by the excess bromine to bromous acid. From a few experiments made to determine the equation governing the formation of bromous acid, the following seems to be most probable:—

Several attempts to isolate the anhydride (Br_2O_3) proved unsuccessful. A few tests, made by adding liquid bromine, in excess, to sodium hydroxide solution, seemed to indicate an oxidation of the sodium hypobromite to sodium bromite.

the exit from vitriol chambers by looking through a three-quarter inch hole in the flue at an angle from its centre. The anemometer showed no velocity just inside the chimney, only a slight oscillation on the surface of the ether. He was glad to hear from Mr. Thorp that by making a lip at the end of the tube the globules were arrested at the sides and accurate delivery was the result. By this means the friction was reduced to a minimum at the point of discharge. As to the width of chimney necessary to obtain the maximum of 2 ins. of eddying matter inside, the gas lining varied with the size of the chimney. It was generally admitted that 2 ins. was the usual amount in most chimneys of average size.

MR. HENRY HOWARD IN THE CHAIR.

THE CONTACT PROCESS FOR MANUFACTURING SULPHURIC ACID OF THE VEREIN CHEMISCHER FABRIKEN IN MANNHEIM.

BY WM. WILKE.

This process is based on the following fundamental principles:

1st. To use the heat of the ordinary roasting process for carrying on the catalytic action of the oxide of iron upon the sulphurous acid.

2nd. The purification of the burner gases is a dry process. In all other processes the gases are washed and have to be dried again.

3rd. The conversion or catalytic oxidation of that part of the sulphurous acid which passed through the iron contact, but had not been converted, is brought about by means of platinum and reheated to the proper temperature by means of the waste heat of the burner gases.

4th. The whole process is carried on by moving the gases by means of exhausters only.

The roast gases leave the kilns at a temperature of about 700° C. This is the proper temperature necessary in the iron oxide to produce the conversion or catalytic action to transform the sulphurous acid into sulphuric anhydride. The iron oxide, at the above mentioned temperature, forms iron arsenate, with the arsenious acid which is contained in the roast gases. If roast gases are taken at the temperature of the furnace through the oxide of iron, a large proportion of the sulphurous acid (50—60 per cent.), is converted into sulphuric anhydride while the arsenic contained in these roast gases combines with the oxide of iron.

Water contained in the gases to be converted reduces the catalytic property of the iron oxide; it is, therefore, necessary to produce the roast gases with dried air. The drying of the air necessary for the process is accomplished with sulphuric acid which is produced in the process.

The roast gases are produced in a furnace which is protected with an air-tight iron shell, against any entrance of moist atmospheric air. The air necessary for the roasting process passes through towers which are scrubbed with sulphuric acid and is then conducted through air-tight pipes entering the furnace or kilns below the grate bars. The dry and hot roast gases so obtained are conducted to a shaft which is attached to the furnace and filled with oxide of iron (pyrites cinders). In this shaft part of the conversion takes place, that is, part of the sulphurous acid is converted into sulphuric anhydride, while at the same time the arsenic obtained in the roast gases is retained.

The roast gases therefore are subjected to a dry purification, and are considerably reduced in their contents of sulphurous acid. After the sulphuric anhydride which is

formed in this first part of the process has been absorbed, the rest of the sulphurous acid contained in the gases can be converted into sulphuric anhydride by means of a very small amount of platinum. To do this, it is necessary to remove any small quantities of sulphuric acid (monohydrate) which have not been absorbed. This is accomplished by passing the gases through layers of porous material which is not affected by sulphuric acid. The main part of the sulphuric acid which is carried over mechanically is eliminated or retained in this way. The purified gases are now allowed to pass through layers of granulated basic blast-furnace slag.

The gases which have passed through the iron contact mass contain sufficient heat to reheat the filtered gases to the temperature necessary for catalytic action in the platinum contact.

It would be possible to utilise this heat by giving it off to the filtered gases. But the sulphuric acid (monohydrate) must be carried along in the form of vapour. The heat, therefore, must not be reduced too much to keep the monohydrate in a gaseous state. The heat given off in the heater located over the iron contact is not sufficient to raise the filtered gases to the temperature necessary to carry on catalytic action in the platinum contact. It is, therefore, necessary to have a small coal fire to raise these gases to their proper temperature.

The platinum contact apparatus must be built in such a way that it does not offer much resistance to the passage of the gases, in order to move them with an ordinary exhauster. This is accomplished by using a number of platinised asbestos nets, the meshes of which are such that the resistance in the whole apparatus does not represent more than the pressure of a column of water about 30 mm. high. In constructing the platinum contact apparatus in this way, it is possible to exchange a single element during the process in the course of a few minutes without interruption. In this process, it is possible to have a conversion of the roast gases up to 95 per cent.

The first plant in the United States was erected in 1903, in the works of the Schoellkopf, Hartford and Hanna Co., in the city of Buffalo, N.Y. This plant consisted then of one unit with a capacity of about 1600 tons of sulphuric acid or its equivalent. The original plant has since been enlarged to four times its original capacity. Besides this plant, four other firms have adopted this process, and there are now in use twenty-two units with a capacity of about 35,000 tons, and in the course of construction, ten more units with a capacity of 16,000 tons. This is a total capacity of over 50,000 tons per year. This has been accomplished in a little over two years since the process has first been introduced here.

This process does not require complicated or delicate pieces of apparatus, a staff of scientific men, nor any special apparatus for the purification of the roast gases, as this is done in the furnace itself. The amount of fuel consumed and motive power required is smaller than in any other known process, and the plant can be built up gradually on account of the units being small and being easily arranged in groups. The cost of repairs is very low.

New York Section.

Meeting held at Chemists' Club, on Friday, November 24th, 1905.

DR. RUSSELL W. MOORE IN THE CHAIR.

THE EXISTENCE OF BROMOUS ACID (HBrO₂).

BY A. H. RICHARDS.

The following experiments were conducted in the laboratory of the Telluride Mill, at Colorado Springs, Colo. :—

The effect of adding a cold aqueous solution of silver

man discussed some of the various systems of costing. Companies and private firms often fell victims to unsound book-keeping and faulty balance sheets. Here the neglect of sound principles led to trouble. He gave an instance of partnership in which an old partner was joined by a new man. Plenty of profit appeared in the balance sheet for division at the end of the year, but there was a deficiency in the money at the bank. There was no suspicion of dishonesty, and an independent expert was asked to investigate. It was then found that all repairs and renewals had been charged at full cost, and even such items as a wall rebuilt and a yard re-paved had been taken into

stock. Depreciation and its influence on future profits, percentages, and the antiquation-factor had all to be carefully considered in determining the position of a business concern. In particular, as regards depreciation, experts were now pointing out that the deduction under this head should be increased as the plant became older.

Mr. Paton then touched upon such expenses as advertising, exhibitions, &c., also on the bearing of the cost of law on industrial enterprise, the effects of trusts and the working of monopolies. Time pressing, he had to bring his address to a close without giving all the illustrations he had intended.

Journal and Patent Literature.

I—PLANT, APPARATUS & MACHINERY.

ENGLISH PATENTS.

Cooling or Heating Liquids; Apparatus for —. A. S. Barham, London. Eng. Pat. 26,578, Dec. 6, 1904.

THE coil, through which the cooling or heating medium is circulated, is hung on pivots, and is rocked to and fro in the liquid to be cooled or heated, by means of an eccentric and suitable gearing.—W. H. C.

Autoclave and Hydraulic Press; Combined —. E. Docauville, Paris. Eng. Pat. 28,539, Dec. 28, 1904. Under Int. Conv., Sept. 10, 1904.

SEE Fr. Pat. 350,167 of 1904; this J., 1905, 1217.—T. F. B.

Drying and Screening Sand, Minerals and other Substances; Apparatus for —. E. Robinson, London. Eng. Pat. 28,684, Dec. 29, 1904.

A HORIZONTAL revolving cylinder is fitted with a continuous internal spiral, each turn of which is provided with lifting plates to assist in agitating the material to be dried. The cylinder is enclosed in a suitable heating chamber, built above a furnace, and has a perforated cylindrical prolongation beyond the end of the heating chamber. This serves to sift the dried material as it leaves the apparatus. The furnace chimney has a concentric jacket, and air is drawn by a fan through the annular space thus formed, and is heated by the hot waste gases. The hot air is then driven through the drying cylinder in the opposite direction to that taken by the material under treatment.—W. H. C.

Separating Solid Substances from Liquids [Drying Beet Slices]; Apparatus for Mechanically —. H. Hencke, Berlin. Eng. Pat. 29,358, Dec. 31, 1904.

THE apparatus consists of a rotating drum connected to a suction apparatus, and upon the surface of the drum the material to be treated is fed continuously. The liquid portion passes through the porous surface of the drum, and the solid matter is removed from the exterior. The claims are for applying the suction to only a portion of the surface of the drum so that the part at which the material is fed or removed is not subjected to suction. Further, an auxiliary suction drum, situated just before the withdrawal scraper, loosens the material from the main drum, and a brush applied just after the withdrawal scraper, cleanses the filter surface of the drum, both the loosening and cleaning being facilitated by the absence of suction at these points. The material is fed from a hopper, provided with regulating blades, between the surface of the main drum and an auxiliary suction drum, which spreads out the material on to the main

drum, so that when the main suction comes into play, as the drum rotates, the surface of the main drum is covered with a continuous layer of material. Further claim is made for a washing trough, provided with cleansing openings for the withdrawal of sediment, in which that portion of the surface of the main drum which is not covered with material may be cleansed. By means of pipes in the bottom of this trough, material for treatment may be supplied at the lowest point of the drum if desired.—W. H. C.

Separators; Centrifugal —. C. Schuler, Grovenbroich, Germany. Eng. Pat. 19,894, Oct. 2, 1905. Under Int. Conv., Nov. 26, 1904.

THE claim is for a centrifugal machine in which the bottom of the basket can be lowered away from the body. The bottom only is attached to the rotating shaft and imparts its motion to the rest of the drum by forming the joint between them as a friction ring. When the bottom, which continues to rotate, is lowered, the upper portion of the basket seats itself on the bottom of the outer casing and comes to rest, the contents of the basket falling out through the annular space left between the bottom of the basket and the casing.—W. H. C.

Oil contained in [Boiler] Feed Water; Estimation of the Quantity of —. W. H. Martin, Flushing, Holland. Eng. Pat. 11,067, May 26, 1905.

THE invention relates to the approximate determination of the amount of oil present in condensed steam intended for boiler feed-water. Several devices are described and claimed for this purpose, all of which are based upon the observation of an object through a column of the water (which is more or less opaque according to the quantity of oil contained in it), and determination of the point at which this object is only just visible.—A. S.

Furnaces; Impts. in —. E. Lane, Kansas City, U.S.A. Eng. Pat. 13,763, July 4, 1905. Under Int. Conv., July 5, 1904.

SEE U.S. Pat. 773,328 of 1904; this J., 1904, 1079.—T. F. B.

UNITED STATES PATENTS.

Filter; Centrifugal —. L. C. Tront, Vantrent, Cal. U.S. Pat. 803,213, Dec. 5, 1905.

THE screen A, supported on the shaft B, at an angle to the horizontal, is rotated in a horizontal plane by the mechanism C C, and is at the same time rotated by the mechanism D D in a plane at right angles to its own axis. The liquid to be filtered is fed on to the upper surface of the screen A from the delivery pipe E; the liquid portion passes through and flows away by the

trough F and the pipe G, whilst the solid matter is delivered on to the platform H.—W. H. C.

Filter-Press. R. Pick, Buffalo, N.Y.
U.S. Pat. 806,491, Dec. 5, 1905.

A FILTER-PRESS comprising a frame with filter-plates and spacing-frames, with filter-cloth clamped between them, has the plates constructed with projections as shown in the figure. Claim is made for these projections 17 and for the arms 14 which extend upwards at an acute angle from the lower front corners of the plates.—W. H. C.

Agitating and Mixing Apparatus — L. C. Trent, Vantrent, Cal. U.S. Pat. 806,214, Dec. 5, 1905.

THE material to be treated is contained in the vessel 1,

and is withdrawn by the rotary pump 8, through the passage 13, 12 and the pipe 10, and returned under pressure through the pipe 6, the junction-piece 5 and the pipe 4 into the rotating reservoir 3. It then passes through the hollow arms 14, and out of the hollow tubes 15, 16, which are set at an angle to the arms 14, as shown at 17. Air may be admitted to the pump for the purpose of aerating the material under treatment.—W. H. C.

Heating-Furnace. W. N. Best, Los Angeles, Cal. Assignor to J. H. and E. Best, Quincy, Ill. U.S. Pat. 806,628, Dec. 5, 1905.

THE furnace consists of a metallic casing lined with refractory material in which there is a longitudinal opening, contracted at each end, which forms the furnace-chamber. The furnace has two "vents"; one of these forms the outlet for the heating flame, and is directly opposite the inlet at the other end of the furnace-chamber, whilst the second rises through the roof of the furnace near the outlet. The furnace is suspended by an adjustable sling, and is provided with hydrocarbon burners at the inlet end.—W. H. C.

Lixivation Processes; Apparatus for — A. W. Constans, Nelson, Canada. U.S. Pat. 805,635, Nov. 28, 1905.

THE claim is for the combination, in a tank, of a central well and elevator with a filter of cloth and wire gauze supported on slats.—W. H. C.

Desiccating Process. J. C. McLachlan, Assignor to International Desiccating Co., Chicago, Ill. U.S. Pat. 806,747, Dec. 5, 1905.

THE claim is for the process of obtaining the solid contents of liquids in the form of a dry powder. The liquid is "atomised" by heated air, free from products of combustion, and the spray is discharged into and allowed to fall through a tall chamber, the air in which is heated by a jacket or coil, in such a way that it is not contaminated by products of combustion. As the particles of spray fall, the liquid portion is evaporated by contact with the heated air, which should not have a temperature higher than 150° F., and passes away from the top of the vessel whilst the solids collect at the bottom as a practically dry powder.—W. H. C.

FRENCH PATENTS.

Filter. H. Lieberich. Fr. Pat. 357,208, July 25, 1905 Under Int. Conv., Oct. 8, 1904.

SER Eng. Pat. 13,247 of 1905; this J., 1905, 1055.—T.F.B

Fire-Resisting Covering of Felt for the Heat Insulation of Pipes, Conduits, &c. H. Kumpf. Fr. Pat. 357,044 Aug. 5, 1905.

THE heat-insulating covering for pipes, conduits, &c. described, consists of shells or other hollow objects of felt, of any required form, which are soaked in a solution of magnesium chloride, or magnesite with aluminum chloride, or a "solution" of cement or other agglomerant after which the objects are pressed into the desired form and on drying become hard, preserve their form, and at the same time are rendered fire-resisting.—W. H. C.

Cooling of Fluids; Apparatus for the Methodical and Fractional — C. Lamhart. Fr. Pat. 356,737 Aug. 7, 1905.

THE apparatus consists of two systems of coil coolers or condensers worked in series. In the first the fluid is partially cooled by means of water or other liquid at the ordinary temperature, and in the second the cooling to the desired extent is completed by using cooled brin or a similar liquid. A smaller quantity of specially cooled liquid is required, as the greater part of the cooling is effected by a liquid at the ordinary temperature.—W. H. C.

Evaporating, Distilling and other similar Apparatus Process for Obtaining a Multiple Utilisation of Heat in — E. Theisen. Fr. Pat. 356,752, Aug. 8, 1905 Under Int. Conv., Nov. 9, 1904.

FANS or other aspirating and blowing apparatus are placed, either in the evaporating chambers, or in the connections between the vaporising chamber of one part and the heating chamber of the next. The pressure in the vaporising chamber is thus reduced, and the gases and vapours are aspirated and delivered, under pressure into the heating chamber of the next unit of the series.—W. H. C.

Distillation; Apparatus for Continuous — J. E. I. Rouaix and O. Simon. Fr. Pat. 356,925, Aug. 14, 1905.

The apparatus consists of two stills 1, 1, used alternately

and provided with charging taps 3, 3, run-off pipes 4, air valves 2, 2, thermometers 5, 5, and steam heating coils, supplied with steam through 8. The vapours pass

from the still 1, into the fractionating column 9, provided with a flattened hollow spiral 10, through which a current of cooling water flows, entering at 11 and leaving by 12. This column, which is a special feature of the invention, is shown in greater detail in figure 2. The spiral 10 has internal gutters 18 in order to distribute the cooling water over the surface, and the column is provided with baffles formed of perforated plates 19, to delay the upward passage of the vapours and to force them into more intimate contact with the cooling spiral, which acts as a partial reflux condenser. The uncondensed vapours pass from 9 by the swan-neck 13 to the special rectangular condenser worm 14 contained in the tank 15, which is fed with cooling water at 16 and has an overflow 17. The section of the worm 14 on the line A-B is shown in figure 3. The horizontal pipes are of the flat oval section shown in order to give a large surface, and they are connected by the smaller pipes of circular section so as to produce a constriction at each bend of the coil. From 14 the condensed vapours pass through a hydrometer box to one of two receivers, which are connected to an air pump and used alternately.—W. H. C.

Centrifugal Machines for Separating Solids from Liquids.
Aktiebolaget Separator. Fr. Pat. 350,910, Aug. 12, 1905. Under Int. Conv., Nov. 18, 1904.

THE claim relates to centrifugal machines in which the solids are withdrawn from the periphery of the drum and transported across the layer of liquid to the outlets near the centre, by means of wheels provided with rakes. The invention consists in introducing additional scrapers, carried on a cross-piece, attached to the shaft which rotates the rake-wheels. The function of these additional scrapers is to carry the solids around the periphery of the drum and to bring them within reach of the rakes on the wheels.
—W. H. C.

Centrifugal Machines for Separating Solids from Liquids.
Soc. Aktiebolaget Separator. Fr. Pat. 357,065, Aug. 10, 1905.

In machines similar to those referred to in the preceding abstract, the rakes on the wheels are constructed in the form of cups, which are either fastened to rotating arms, or are held between annular discs. The bottom of the cup is made lower than the edge to facilitate the collection of the solid particles.—W. H. C.

II.—FUEL, GAS, AND LIGHT.

Incandescent Mantle as a Catalyst and its Application to Gas Analysis. J. E. Mason and J. Wilson. Chem. Soc. Proc., 1905, 18, 296.

THE method described by Lowes (this J., 1905, 124) for demonstrating the incandescence of the ordinary gas mantle in a cold mixture of coal gas and air may also be employed with a mixture of ammonia vapour and air. The authors describe a modification for showing the incandescence of the mantle in an unburnt mixture of alcohol vapour and air. Although less effective, the mantle may be used as a substitute for platinised asbestos in the ordinary lecture experiments for preparing formaldehyde from methyl alcohol vapour and air, and sulphur trioxide from sulphur dioxide and oxygen.

Fragments of mantle in a hard glass or preferably quartz tube may be used in place of palladium or palladium-asbestos, for the estimation of hydrogen and carbon monoxide in gas analysis by combustion with excess of air or oxygen. Methane and mixtures of methane and hydrogen may be estimated similarly by passing these gases mixed with excess of oxygen over fragments of mantle heated in a quartz tube, and measuring the contraction after combustion, and subsequent treatment with caustic potash solution. The results agree well with those obtained by the customary explosion methods. Good results may also be obtained by passing the gases mixed with oxygen over asbestos heated in a small quartz tube. Hydrogen, and less readily methane, may be determined by passing the gas mixed with oxygen through narrow tubes of heated Jena glass alone.

ENGLISH PATENTS.

Furnaces; Regenerative Gas — G. Hatton, Brierley Hill, Staffs. Eng. Pat. 29,610, Dec. 31, 1904.

THE furnace is constructed with two regenerator chambers provided with a slide-valve. The gas and air always enter the furnace at the same end, and the waste gas passes through the regenerators alternately. The air is heated by being drawn through that regenerator through which the gas is not passing, and by altering the position of the slide-valve the directions in which the currents of waste gas and air flow can be reversed.—W. H. C.

Air, Gas, or the like Fluids, for Gasifying Hydrocarbons; Pressure-raising Apparatus for — or for other Purposes. W. S. Gillie, Edinburgh. Eng. Pat. 25,477, Nov. 23, 1904.

THE bell of a gas-holder is connected, by means of a lever, with a small external hydraulic pump, which causes the bell to rise and fall, thus delivering air into a second gas-holder, from which the air is supplied to a carburetter. The water supply to the pump is controlled by the rising or falling of the second gas-holder, so that the pump ceases to operate when the holder is full. The first holder may be single-acting, in which case the surrounding cylinder is open at the top, or the cylinder may be closed to render the holder double-acting, the inlet and outlet valves for the air being arranged accordingly. An automatic three-way cock on the water-supply pipe brings about the reversals of the pumping strokes when due.—H. B.

Gases; Purification of Furnace — W. Schwarz, Dortmund, Germany. Eng. Pat. 29,360, Dec. 31, 1904.

SEE Fr. Pat. 350,592 of 1905; this J., 1905, 794 —T. F. B.

Briquette Fuel from Coal Mine Waste or Dust Coal; Manufacture of — T. Ronse and H. Colin, London. U.S. Pat. 806,845, Dec. 12, 1905.

SEE Eng. Pat. 9071 of 1904; this J., 1905, 611.—T. F. B.

Gases; Apparatus for Cleaning Manufactured — L. P. Lowe, San Francisco. U.S. Pat. 805,653, Nov. 28, 1905.

THE apparatus consists of a circular shell or chamber, into which the gas-inlet pipe descends vertically, at the centre, for some distance. The inlet pipe is constricted near its lower end, and a steam-pipe discharges into the constricted portion. A certain amount of water is allowed to collect at the bottom of the chamber, the level of the water being maintained constant by an overflow pipe on the side of the chamber, provided with a water seal. The gas-inlet discharges directly downwards towards the surface of the water, but the discharge aperture is wholly above the water level. By this arrangement, and the steam supply, the heavier particles are projected into contact with the water, whilst the lighter gaseous particles escape contact with it, and pass up through the upper portion of the chamber to the gas-outlet near the top. Means are provided for subjecting the gas to a continual discharge or spray of water in the upper portion of the chamber.—W. C. H.

Gas-Purifier. M. F. McNelly, Chicago. U.S. Pat. 805,985, Nov. 28, 1905.

THE purifier consists of several chambers, one of which contains a liquid and receives the flow of gas. From this chamber the gas passes into a recess or pocket, provided with finely-perforated walls, and arranged within a dry chamber. The gas passes into this dry chamber, which is filled with circular or cylindrical pieces of material, having a pitted or rough surface, around and over which the gas passes, and also a pith-like surface through which the gas is forced to pass on its way to the point of consumption.—W. C. H.

Ammonia and Hydrocyanic Acid; Process of Recovering — [from Gas] W. Feld, Hönningen-on-the-Rhine. U.S. Pat. 806,467, Dec. 5, 1905.

SEE Fr. Pat. 341,614 of 1904; this J., 1904, 861.—T. F. B.

Incandescent Mantles; Machine for Manufacturing — J. L. Muller, Sannois, and J. Bonnot, Paris. U.S. Pat. 805,930, Nov. 28, 1905.

FRENCH PATENTS.

Agglomeration [Briquetting] of Anthracite Dust; Process for the — A. Exbrayat. Fr. Pat. 350,258, Oct. 25, 1904.

SEAWEEDS (fucus) or lichens are treated with hot or cold water, either with or without the addition of an alkali, and the gelatinous mass obtained is mixed and heated with resin. The product is then mixed with anthracite dust and briquetted.—W. H. C.

Agglutinant and Combustible Agglomerant; Process for the Manufacture of a New — and Briquettes formed with such Agglutinant. R. A. Le Maître, J. A. Badjou, and M. V. F. Bekaert. Fr. Pat. 356,961, Aug. 18, 1905. Under Int. Conv., May 2, 1905.

THE products resulting from the action of a mixture of nitric and sulphuric, or of nitric and hydrochloric acids on organic bodies of animal origin, such as blood, faeces, suint, cholesterol, crude lanoline, products from the treatment of waste water from wool washing, &c., are caused to act, in the presence of a "condensing agent" such as baryta, caustic lime or sodium hydroxide, zinc or aluminium chloride—on heavy hydrocarbons, or the residues of the distillation of such bodies. For instance, 100 parts of suint are treated with 2 parts of a mixture of 2/5 sulphuric and 3/5 nitric acid, and the reaction is stopped by the addition of an alkaline solution when red vapours of the oxides of nitrogen begin to be evolved. The product is dried and heated in an autoclave with 1000 parts of heavy mineral oil and 10 parts of baryta until resinification of the mass takes place. The resulting product is mixed with powdered coal, coke, charcoal, &c., to form briquettes, or it may be moulded and used as an agglomerant for other purposes. Claim is also made for the preliminary heating of coal dust in a reducing atmosphere and for the use of wood charcoal saturated with combustible gases to form briquettes.—W. H. C.

Peat and other Similar Combustible Matters, Rich in Water; Process and Kiln for the Semi-Carbonisation of — Oberbayerische Kokswerke und Fabrik Chem. Prod. Akt.-Ges. Fr. Pat. 357,174, Aug. 24, 1905.

THE peat is charged into the kiln B, provided with the

funnels f and f' , to better distribute the gases introduced by the pipes h and e . In the upper part of the kiln B, the peat is treated either with gaseous and smoke products aspirated by the fan d from the flues a of the retort furnace A, and delivered by the pipes c , g , the valve i and the pipe h , just below the funnel f ; or through g' with steam, superheated in the coil l , in the auxiliary furnace m , fed with gas by the pipe n and with air through o . The steam and other products escape by the pipe q , to the valve-box r , from which they either escape by s , or pass to a condenser. In the lower part of B, the peat which has been dehydrated in the upper portion of the kiln, is treated with the smoke-gases from A, which are brought by the pipe c and the valve e , below the funnel f . The peat is semi-cooked, and the products given off in the lower part of B, escape by the pipe u and the valve v , either to the air, or to a condenser through w .—W. H. C.

Furnace; Rotary — for the Production of Gas, or for Roasting [Ores, &c.]. S. E. Sienrin. Fr. Pat. 356,615, Aug. 3, 1905.

THE furnace consists of an inclined cylinder that can be rotated, and is provided with a number of separating partitions, arranged transversely to its axis. The separate compartments thus formed communicate with one another through apertures in the partitions. By this means the passage of the materials through the furnace is prolonged, and the gases are forced to pass through and not only over the materials, the reaction zone being thus increased, whilst the continuous mixing of the materials ensures more complete treatment. The materials are fed into a hopper forming part of a casing which is fixed gas-tight upon the upper end of the cylinder, and the ash passes out into a casing fixed gas-tight at the lower end and falls into a water chamber. Air is forced into the casing at the lower end, and gas escapes from the upper casing. — W. C. H.

Gas-Retorts; Furnace for Vertical — J. Bueb. Fr. Pat. 356,974, Aug. 18, 1905.

THE retort furnace comprises a gas generator, recuperators for heating the air for combustion, and a series of vertical retorts placed one behind the other, in one or more rows. The burning gases enter the retort chamber horizontally at the bottom, and are caused to pursue a zig-zag upward course round the retorts, by means of horizontal baffles in which the retorts are set, and by means of dampers or the like the retorts can be heated in each zone proportionately to their cross-section. The furnace is designed particularly for vertical retorts the diameter of which gradually decreases towards the top (see Fr. Pat. 339,534; this J., 1904, 709).—H. B.

Gas and Air; Process for Accelerating the Combustion of Mixtures of — Gas-Motoren Fabrik Deutz. Fr. Pat. 356,599, Aug. 2, 1905. Under Int. Conv., Aug. 5, 1904.

THE process described for accelerating the combustion of mixtures of gas and air, and rendering the combustion as rapid as possible, and consists in bringing two currents of gaseous mixtures separately to the point of combustion; one of the two currents is composed of a quantity of air insufficient for combustion of the gas with which it is mixed, and the other of a quantity of gas insufficient for combustion of the air with which it is mixed. The actual combustion takes place in a combustion chamber to which these gaseous mixtures are brought by two separate pipes, controlled by valves. The requisite mixtures are obtained in the parts of the pipes on the sides of the valves away from the chamber; and the mixture is effected by connecting the air-supply pipe by a small off-take pipe, controlled by a valve, with the gas-supply pipe and by a similar arrangement allowing a small amount of gas to pass into the air-supply pipe. Thus two separate mixtures, in any desired ratio, can be obtained separately and brought to the combustion chamber.—W. C. H.

Carburettor applicable to Fired or Movable Motors, working with Tar Oils, Petroleum or Mixtures of these Bodies. A. Canera di Salasco and E. Manassero. Fr. Pat. 356,603, Aug. 2, 1905.

THE principle on which the apparatus acts, is that a current

of air, divided into very fine streams and driven at a high speed, encounters over a large surface, a very small volume of oil or other liquid. The essential components of the apparatus are a float, together with a spherical plug and arrangements for producing the very fine division of the liquid and its intimate mixture with the air to be carburetted. When connected with the reservoir, the carburetted liquid raises the plug and then the float and escapes up a vertical pipe, through a fine nozzle, and the float then sinks and the plug closes the entrance for the liquid. The aspirating stroke of the piston at the same time causes air to enter through a number of fine holes, and this air is simultaneously mixed with the fine jet of carburetted liquid.—W. C. H.

Compressed Gas; Method of Producing — for use as Motive Power. A. P. Elten. Fr. Pat. 356,949, Aug. 16, 1905. Under Int. Conv., Aug. 17, 1904.

Two similar explosion cylinders communicate with each other by means of the pipe c , and are charged with water or other suitable liquid; they also communicate with a receiver t , for the compressed gas. The accompanying figure shows the state of affairs at the beginning of the cycle of operations; the air in a , and in the bell-shaped chamber d is under atmospheric pressure, the slide-valve l closes the openings into the tube j , and the valve n is kept closed by the compressed gas in t , whilst the air in b and e is under compression. Combustible gas is now injected into e at g , ignition of the charge takes place at e , and the gaseous products of the explosion, raising the valve o , are discharged into receiver t , whilst giving at the same moment an impulse to the water that drives it partly into a and d , compressing the air therein. The water thus acts as a piston. As the water continues to fall in b and e , air is drawn in at the top of e , the slide-valve m having moved in tube k so as to open communication with the atmosphere. When the water has reached its lowest level in b , the state of affairs is the same as it was in a at the outset; combustible gas is now injected into d at p , exploded, the gas collected in t , and the water-piston given an impulse towards b —and so on.—H. B.

Gas-Washing Apparatus. Comp. pour la Fabrication des Compteurs et Matériel d'Usines à Gaz. Fr. Pat. 356,721, Aug. 7, 1905.

THE object of the invention is to produce a gas washer with a larger surface of material unattainable both by the gas and the liquid, and to give automatically to both fluids a methodical impulse, or to allow their displacement in the same sense. In the simplest form suggested, the apparatus consists of a gas channel in which a cylinder just fits transversely, and rotates on its axis. The channel is half filled with liquid and half with gas. The cylinder is filled with inert material designed to give a large surface of contact. The rotation of the cylinder, through which the liquid flows, causes a depression on one side and a corresponding elevation on the other, and the upper half of the cylinder presents a large surface of contact between the two fluids.—W. C. H.

Naphthalene from Coal Gas; Apparatus, called "Naphthalene Trap," for Removing — Comp. Parisienne d'Eclairage et de Chauffage par le Gaz. Fr. Pat. 357,045, Aug. 7, 1905.

THE "naphthalene trap," which is inserted into the gas main, consists of a casing, containing one or more bodies

over which the gas flows. Each baffle is formed of a sort of grill, the closely-set bars of which consist of metallic tubes of small diameter (8 mm.), through which cold water or air can be circulated continuously. A thin metal plate, having a large number of slots, is fixed against the grill and, cooled by conduction, presenting a large cooled surface, upon which the naphthalene is precipitated. When the naphthalene has accumulated sufficiently to obstruct appreciably the flow of the gas, the latter is by-passed, and steam is circulated through the tubes of the grill, whereby the naphthalene is liquefied and flows through a siphon to the exterior of the trap. The trap is then allowed to cool, and the passing of the impure gas is resumed.—H. B.

Incandescent Filaments; Manufacture of —. A. Frankfurter and H. Kuhlmann. Fr. Pat. 356,999, Aug. 17, 1905.

ELECTRIC-LAMP filaments, electrodes, anodes for Röntgen apparatus, &c., are made from graphite which has been "purified chemically," the graphite being moulded, in a dry state, into the desired form under "high pressure." —H. B.

Incandescent Lighting; Process of Extracting a Metal for Making Mantles for —. M. Danziger, W. Krounheim, R. Hochhauser, H. Eisler and H. Reeser. Fr. Pat. 357,077, Aug. 21, 1905.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Petroleum Production of Canada. U.S. Geological Survey, through Board of Trade J., Dec. 28, 1905.

IN 1904, the new Leamington oil field produced 25,241 barrels of petroleum, which was no increase of about 24,000 barrels over that of 1903. This field is situated near the former natural gasfield in the south-eastern portion of Essex County. The Moore field, situated in Moore Township, Lambton County, is noted for the first time with a production of nearly 37,000 barrels. A well producing twelve barrels of petroleum per day was drilled in Southern Alberta, near South Kootenay Pass. There are numerous natural developments of petroleum and natural gas on the eastern flank of the Rocky Mountains, extending from the United States line to the Arctic Ocean, which in the future will, in all probability, produce large quantities of petroleum.

There were several new wells drilled in the New Brunswick field that were productive of petroleum suitable for lubricating purposes. For the past three years there have been active operations in New Brunswick, near Memramcook, a few miles south of Moncton. There are two fields now being worked, four or five miles apart, known as the Dover and St. Joseph's College. During 1904 there were from 18 to 25 wells pumped in each of the fields, most of the production being from thirty wells, and amounting to about 50 barrels per day. There are two varieties of petroleum produced, one quite black, and the other dark green. The specific gravity is nearly the same, from 35° to 37° B. The construction of a refinery has been commenced. [T. R.]

Petroleum; Reduction of Egyptian Import Duty on —. Board of Trade J., Dec. 14, 1905.

THE Egyptian "Journal Official," of Nov. 25, contains the text of a decree, which is already in force, reducing the import duty on petroleum from 8 per cent. to 4 per cent. *ad valorem*. [T. R.]

ENGLISH PATENTS.

Loke Ovens; Impts. in —. H. Koppers, Essen-Ruhr, Germany. Eng. Pat. 25,527, Nov. 23, 1904.

THE coke oven is provided with vertical combustion-chambers, having the gas and air supply from below; the

masonry at the top of the flues, which fixes them relatively to each other, is provided with slide-controlled passages through which the hot gases pass into an upper horizontal channel, that leads them to the chimney. —H. B.

Paraffin Wax; Apparatus for Treating —. N. M. Hendersoo, Broxburn, N.B. Eng. Pat. 7630, April 11, 1905.

THE invention relates to the process described in Eng. Pat. 11,979 of 1891 (this J., 1892, 599). The cells are very high in proportion to their sectional area, and are provided with a vortical draining screen of wire gauze or the like, and with a false bottom of like material, underneath which is a discharge. If the cells are cylindrical, the wire gauze screen is arranged upon a central cylindrical partition. The cells are arranged in pairs in a "sweating" house, the sides fitted with the draining screens being adjacent to each other and separated by a smaller space than the other sides. The draining is effected by the pressure of the superincumbent column of wax, the screens acting as draining wicks, and the solidification of the wax taking place first at the "unscrewed" ("unscreeded" in the prov. spec.) surface of the cells. —C. S.

Hydrocarbons such as Petroleum and Benzine; Solidification of —. W. van der Heyden, Paris. Eng. Pat. 19,540, Sept. 27, 1905. Under Int. Conv., Oct. 26, 1904.

UNITED STATES PATENTS.

Wool; Apparatus for Treating Resinous — [to Extract the Resins, &c.]. E. B. Weed, Cleveland, Assignor to Weed Distilling and Manufacturing Co., New York. U.S. Pat. 805,174, Nov. 21, 1905.

THE apparatus consists of a retort or still for holding the wool to be treated, a boiler heated by a furnace, to contain the preserving and distilling liquid, a pipe, supplied with a pump and valve, connecting the boiler with the retort, and a second valved coiled pipe, passing through a heating apparatus, connecting the pump with the still, so that hot or cold liquid can be supplied to the still as desired; another valved pipe forms a connection between the portions of the inlet pipe on either side of the pump, so that, by suitably adjusting the valves, the liquid can be returned from the still to the boiler without reversing the pump. —T. F. B.

Vaseline; Process for the Preparation of Water Soluble —. F. Boleg, Canstatt, Assignor to Ges. zur Verwerthung der Bolog'schen Wasserlöslichen Mineralöle und Kohlenwasserstoffe, Berlin. U.S. Pat. 805,443, Nov. 28, 1905.

FRENCH PATENTS.

Stones containing Combustible Matter from Mines; Process for Rendering — Applicable as Filling Material. H. Koppers. Fr. Pat. 356,578, Aug. 1, 1905.

THE stones containing carbonaceous matter from the sorting and washing of coal, as well as the shale which accompanies coal in the mine, are first distilled in vertical ovens to obtain residual products and gas. The residue is then charged hot into a producer, the gas from which may be used to effect the first treatment. In this way the water and volatile matters are first distilled off, leaving a hot residue which is free from moisture, and which is easily gasified in the producer, the heat stored up in the residue serving to ensure regular and constant work. The yield of residuals, especially ammonia, is said to be high, and the burnt residue from the producer forms good material for filling up the abandoned workings in the mine, as it is free from pyrites and carbonaceous matter. —W. H. C.

Ammonia; Extraction of — from Gaseous Products of Destructive Distillation. Soc. F. Brunck. Fr. Pat. 356,539, Aug. 1, 1905.

GASES produced by the destructive distillation of coal, wood, peat, &c., are subjected, before being led into an acid for absorption of the ammonia, to centrifugal action, in order to free them from tarry matters. (Compare Eng. Pat. 8287 of 1903; U.S. Pat. 773,784 of 1904; and First Addition to Fr. Pat. 331,077 of 1903; this J., 1903, 795; 1904, 1147; and 1905, 432.)—E. S.

Hydrocarbons [Petroleum, Tar Products, &c.]; Separation of Carbon from —. H. Koppers. Fr. Pat. 356,351, July 24 1905.

WHEN a spray of liquid hydrocarbon, such as petroleum or a tar product, is introduced into a heated atmosphere of carbon dioxide or a mixture containing it (e.g., furnace gases), carbon is separated from the hydrocarbon, carbon monoxide and water being formed at the same time. The form of carbon produced, depends on the conditions of the reaction; thus, at low temperatures and with an excess of hydrocarbon, the carbon is obtained in the form of soot, whilst at higher temperatures, and especially in presence of "fixed carbon," or inorganic matter such as clay, the carbon tends to separate as graphite. The reaction may be applied to the coating of coke with a deposit of finely divided carbon, by allowing the substances to react in presence of a mass of incandescent coke; this is stated to considerably increase the calorific power of the coke, by diminishing the surface, and is of value in metallurgical processes, preventing premature reactions between the gases and the coke.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

p-Diaminodiphenylamine; New Method of Formation of —. P. Barbier and P. Sisley. Bull. Soc. Chim., 1905, 33, 1232—1234.

THE authors find that *p*-aminophenylphenylhydrazine can be converted into *p*-*p*-diaminodiphenylamine, according to the equation:— $C_6H_5.NH.NH.C_6H_4.NH_2 = NH_2.C_6H_4.NH.C_6H_4.NH_2$. 23.5 grms. of finely powdered *p*-aminoazobenzene hydrochloride were treated with 350—400 c.c. of a saturated aqueous solution of sulphurous acid and 15 grms. of 65 per cent. zinc dust were added, with stirring, until the liquid was decolorised. It was then poured into a mixture of 50 grms. of sulphuric acid with 50 c.c. of water, and allowed to stand over night. The sulphate of *p*-diaminodiphenylamine separated out in the form of grey crystals, which yielded the base on boiling with a slight excess of sodium carbonate solution. The aminoazo-derivative of *o*-toluidine, when treated in the same manner, yielded a *p*-diamino-base which the authors conclude, from its mode of preparation and reactions, to be *p*-diaminoditolyldiamine.—E. F.

FRENCH PATENTS.

Dyestuffs; Production of New Nitroaliphylacidylaminonaphtholsulphonic Acids, Nitroaliphylaminocidylaminonaphtholsulphonic Acids, Aminoaliphylacidylaminonaphtholsulphonic Acids or Aminoaliphylaminocidylaminonaphtholsulphonic Acids and of New Azo — derived therefrom. Société pour l'Ind. Chim. à Bâle. Second Addition, dated May 20, 1905, to Fr. Pat. 321,640, May 31, 1902 (this J., 1903, 210; see also Eng. Pat. 13,778 of 1902; this J., 1902, 1374).

THE process of the main patent is altered by condensing 1,2-diaminonaphtholsulphonic acids, instead of aminonaphtholsulphonic acids, with nitroaliphyl acid chlorides. The substances obtained have the general formula $(\text{NH}_2)(\text{NH}.\text{CO}.\text{R}.\text{NO}_2)\text{C}_{10}\text{H}_5.\text{n}(\text{OH})(\text{SO}_3\text{H})_n$, and on reduction are converted into the corresponding aminoaliphylacidylaminonaphtholsulphonic acids. These substances, like other acidyl-o-dianilines have a strong tendency to separate a molecule of water, and they are isolated in the form of an inner anhydride.

The new dyestuffs claimed, are prepared (1) by combining these anhydrides with diazo- or tetrazo-bodies; (2) by further diazotising the dyestuffs so produced and combining them with amines or phenols either in substance or on the fibre; (3) by diazotising the anhydrides or the hydrated bases and combining them with amines or phenols, and then combining the monoazo dyestuffs thus obtained, with diazo- or tetrazo-bodies. The following examples are given:—(1) Anhydro-*m*-aminobenzoyl-1,2-diamino-5-hydroxynaphthalene-7-sulphonic acid is prepared by reducing the condensation product of 1,2-diamino-5-hydroxynaphthalene-7-sulphonic acid and *m*-nitrobenzoyl chloride. (2) This substance is combined with diazotised *m*-xylidine in a solution made alkaline with sodium carbonate. The reaction product is stated to dye unmodanted cotton in "blue" shades and to yield a bright scarlet of great fastness to washing after diazotisation and development on the fibre with β -naphthol. (3) Anhydro-*p*-aminobenzoyl-1,2-diamino-5-hydroxynaphthalenesulphonic acid is combined in alkaline solution with diazotised *p*-aminoacetanilide, and yields a bluish-red direct dyestuff, which may be diazotised and developed on the fibre to a bluish scarlet and to possess great fastness to washing. Other diazo-bodies may be employed, such as those of aniline, *o*- and *p*-toluidine, *p*-xylidine, *m*-phenylloxamic acid, α - and β -naphthylamine, dehydrothiolimidine, &c., or tetrazo-bodies, such as tetrazotised paradianilines, diaminoazoxybenzene, diaminoazobenzene, diaminoazophenylurea, &c. Other sulphonic acids of 1,2-diaminonaphthol, such as 1,2-diamino-5-hydroxynaphthalene-3,7-disulphonic acid, and also other nitro-aliphylacidyl chlorides may be used for preparing the condensation products, such as *o*- and *p*-nitrobenzoyl chloride, and methyl, halogen, or alkoxy derivatives of the nitrobenzoyl chlorides. Instead of the nitroaliphyl acid chlorides the corresponding acetaminosalicylic acid chlorides may be employed, and in this case the condensation products are hydrolysed with dilute mineral acids to obtain the required amino bodies or their anhydrides.—H. L.

Anthracene Derivatives and Dyestuffs [Anthracene Dyestuffs]; Production of a Series of New — and their Application in Dyeing and Printing. Badische Anilin und Soda Fabrik. Fifth Addition, dated June 22, 1905, to Fr. Pat. 349,531, Dec. 21, 1904. (See this J., 1905, 192, 726, 840, 841, 1010.) Under Int. Conv., Feb. 2, 1905.

IN addition to the substances already claimed, the homologues of the hydroxyanthraquinones, naphthanthraquinones and their reduction products and those of α -aminoanthraquinone may be condensed with glycerol or one of its anhydrides or esters or compound esters.—H. L.

Anthracene Derivatives and Dyestuffs [Anthracene Dyestuffs]; Production of a Series of New — and their Application in Dyeing and Printing. Badische Anilin und Soda Fahr. Sixth Addition, dated June 22, 1905, to Fr. Pat. 349,531 of Dec. 21, 1904. (See preceding abstract.) Under Int. Conv., April 14, 1905.

BENZANTHRONES are converted into new "vat" dyestuffs

for cotton by the action of alkali. Thus 10 kilos. of α -benzanthronequinoline (prepared from α -aminocanthraquinone) are mixed with 50 kilos. of caustic potash and 40 kilos. of absolute alcohol at 160° C., and gradually heated to 220°—230° C. with good stirring. After purification, a new product is obtained, which dyes cotton from a hydrosulphite vat in blue shades of great fastness.—H. L.

Indigo; Production of Leuco Derivatives of —. Deutsche Gold- und Silber-Scheide-Anstalt vorm. Roessler. Fr. Pat. 350,500, July 31, 1905. Under Int. Conv., Aug. 13, 1904.

A METHOD of producing leuco-derivatives of indigo by melting certain benzene derivatives, such as phenylglycine, with an alkali amide in presence of alkali hydroxide is already known. According to the present invention the alkali amide is partially or entirely replaced by alkali metal and relatively small amounts of alkali amide or ammonia. The ammonia forms alkali amide, this reacts with the benzene derivative, re-forming ammonia, and the cycle of reactions is repeated indefinitely. The necessary ammonia may be produced by initially adding to the melt some compound, such as urea, which decomposes and yields ammonia under the conditions present in the melt. The most satisfactory method of carrying out the reaction is to pass gaseous ammonia into a melt containing an alkali metal, alkali hydroxide, and a suitable benzene derivative. For example, 1000 grms. of a mixture of sodium and potassium hydroxides are melted in a closed vessel provided with a stirrer; after expelling the air by means of a current of gaseous ammonia, which is passed through the melt, 120 grms. of sodium are added, followed by 425 grms. of the potassium salt of phenylglycine in small quantities. During these operations a slow current of ammonia is maintained. The addition of the phenylglycine takes about 45 minutes. After it is all added the melt is still heated for a short time, in a gentle current of ammonia, until the reaction is completed. The most suitable temperature is 200° C., and about 20 litres of ammonia are introduced altogether. Prolonged contact of the final product with excess of alkali amide is disadvantageous.—E. F.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Wool, Goat Hair, and Camel Hair; Sorting, Willying, Washing, Combing and Carding —. Statutory Rules and Orders, 1905, No. 1293.

A PAMPHLET of regulations, dated Dec. 12, 1905, has been issued by the Secretary of State, relating to processes of sorting, willying, washing, combing and carding wool, goat hair and camel's hair and processes incidental thereto. The regulations came into effect on Jan. 1, 1906. [T.R.]

Wool Rugs; Dyeing and Dressing of —. J. W. Lamb. J. Soc. Dyers and Col., 1905, 21, 322—326.

Preparation of the Skins.—The skins are first sorted and cleansed from paint or tar marks with turpentine or naphtha.

Soaking and Washing.—After "trimming," the skins are "fleshed" over the beam, and then washed in water to remove blood and dirt. To prevent putrefaction, a little antiseptic should be added to the wash waters. Thorns, &c., are removed by the "burring" machine.

Scouring.—The skins are well scoured by hand, on both sides, with a strong solution of soft soap to which either sodium carbonate or ammonium carbonate is sometimes added. They are then rinsed in tepid water and the scouring repeated if necessary, the skins being finally hydro-extracted.

Leathering.—A mixture of aluminium sulphate or potash alum with common salt, is rubbed into the flesh side until the skin is fairly dry; after leaving over night the process is repeated. In some cases a tepid solution of

alum and salt is painted on. Basic aluminium sulphate gives a tannage which is faster to water.

Bleaching.—For black rugs this is unnecessary, but for light colours the skins are bleached either in a sulphur stove or by means of hydrogen peroxide or potassium permanganate. This is done in a similar manner to the bleaching of ordinary wool, except that a low temperature (not above 40° C.) must be employed. If the skins are to remain white they are well scoured, washed, drained, hydro-extracted, re-tanned if necessary, and degreased by covering the flesh side with a thick paste of whitening and water and drying in a warm room. The whitening absorbs grease. Skins which are to be dyed are usually "chlored" by soaking in a weak solution of bleaching powder and then in dilute sulphuric acid.

Dyeing.—Alum-tanned leather will not stand a temperature above 40°–45° C. without injury, so dyestuffs must be chosen which will dye readily at this temperature. The basic colours are largely used, the dye-bath being heated to 40°–45° C. and a little acetic acid added. The fastness of the colour to rubbing is increased by passing through a solution of some tannin material, such as sumach. By soaking in a tannin solution and then in one of potassium titanium oxalate a good yellowish-brown is obtained. The acid colours are dyed with the addition of a little sulphuric or formic acid. The dyed skins are washed and re-tanned if necessary. To give the wool a gloss, the skins are passed through a hot fat emulsion such as an emulsion of olive oil in soap solution. The skins are dried, softened, combed and beaten, when they are finished. There is at present no satisfactory method of dyeing black on skins with coal-tar dyestuffs and use is always made of logwood. The chief methods used are the "one solution" and the "two solution" methods. For the "one solution" method, 100 lb. of logwood extract, 18 lb. of fustic, and 10 lb. of verdigris are dissolved in 400 galls. of water. The bath is heated to 40° C., the skins entered and soaked for three to four hours, then 3 galls. of acetate of iron are added and the goods are left in until black, which usually requires thirty to forty hours. The above quantities are enough for 5 doz. good-sized skins. In the "two solution" method the goods are soaked first in a solution of logwood and fustic and then in a solution of bichrome, both operations being repeated if necessary. After dyeing black the skins are allowed to oxidise as long as convenient, washed in warm water and scoured with soft soap to give them a gloss; they are again washed and hung up for two to three hours to oxidise, and finally finished like the coloured skins.

The scouring and oxidising processes are of great importance in obtaining a good black.—A. B. S.

ENGLISH PATENTS.

Wool and other Filamentous Materials; Apparatus for Washing ——. P. Bastin, Rouhaix, France. Eng. Pat. 4371, March 2, 1905. Under Int. Conv., Nov. 28, 1904.

SEE FR. Pat. 349,243 of 1904; this J., 1905, 671.—T. F. B.

Fibres; Treating Vegetable ——. chiefly Cotton, Raw or Manufactured, to Render them less Inflammable. The Calico Printers' Association, Ltd., Manchester, and W. Warr, Staleybridge, Lancs. Eng. Pat. 25,166, Nov. 19, 1904.

VEGETABLE fibres or fabrics are rendered less inflammable by immersing them in a solution (about 22° T.) of a magnesium salt, preferably the sulphate, and then in a solution of caustic soda of about the same strength, to precipitate magnesium hydroxide in the fibres; the treatment may be repeated twice or more if desired.

—T. F. B.

Fibres; Treating Vegetable ——. chiefly Cotton, Raw or Manufactured, to Render them less Inflammable. The Calico Printers' Association, Ltd., Manchester, and W. Warr, Staleybridge, Lancs. Eng. Pat. 25,167, Nov. 19, 1904.

AN insoluble magnesium salt, other than the hydroxide (see preceding abstract), is precipitated in vegetable fibres or fabrics to render them less inflammable; the

fabrics are first impregnated with a solution of magnesium sulphate, and then treated with the second component to precipitate the insoluble compound, e.g., sodium silicate or phosphate may be used.—T. F. B.

Dyeing and Printing [with Benzanthrone Dyestuffs]; Impts. in ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 29,501, Dec. 31, 1904.

To apply in dyeing the dyestuffs of the benzanthrone group, described in Eng. Pat. 16,538 of 1904, and 853, 3819, and 7022 of 1905 (this J., 1905, 494, 541, 669, 726, 796, 1010 and 1107), a vat is prepared by reducing the dyestuffs, in the presence of alkali, with sodium hydro-sulphite. In this textile materials to be dyed are immersed for about three-quarters of an hour, at a temperature varying according to the dyestuff employed, from 60° to 90° C. They are afterwards washed, dried, treated with acid, and again washed. Cotton tissues, &c., are thus dyed by the dyestuff, prepared from the condensation product of β -aminoanthraquinone and glycerol, in dark violet-blue shades, which, it is stated, are of excellent fastness to light, washing and chlorine. For printing with the dyestuffs of this group, two methods are available:—(1) A thickened alkaline mixture of a benzanthrone dyestuff, stannous hydroxide or a hydro-sulphite or other reducing agent, and glycerin, is applied to the textile materials, which are thereupon dried, steamed for five to ten minutes in an atmosphere as free as possible from air, rinsed in water, and washed in a bath of sodium carbonate. (2) The (cotton or linen) tissues, &c., are printed with a thickened mixture of the dyestuff, ferrous sulphate and stannous chloride, dried and passed for about a minute into a bath of caustic soda-lye (containing 10–12 per cent. of sodium hydroxide), heated at 65°–75° C. The tissues, &c., are then washed with water, treated with an acid to remove the iron oxide, and again washed. To prevent the unprinted parts from becoming stained, a little manganese dioxide may be added to the caustic soda bath. (See also this J., 1905, 192.)—E. B.

Carpets; Improved Machine for Washing or Dyeing ——. G. Kolling, Klein-Tschansch, Germany. Eng. Pat. 17,960, Sept. 5, 1905.

CARPETS, more particularly those of large dimensions, which are to be washed or dyed, are drawn between a rotary brush-roller and a trough-shaped supporting-table, soap- or dye-liquor being forced into them as they pass along the table, from a perforated pipe mounted in front of the brush. They are thus saturated with the liquor applied to them before they enter the trough, where they are operated upon by the brush, which is revolved in a direction opposite to that in which they are moving, while they are immersed in the liquor which collects in the trough. They are finally passed between squeezing-rollers.—E. B.

Formaldehyde Sulphoxylate [Discharging Agent]; Manufacture of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 21,538, Oct. 23, 1905.

FORMALDEHYDE sulphoxylate salts are obtained by the following methods, in addition to those already described (this J., 1901, 247; 1904, 369 and 900; 1905, 132, 329 and 330):—(1) Normal zinc sulphite is acted upon, in boiling aqueous solution, with zinc dust and formaldehyde. The difficultly soluble, basic zinc sulphoxylate salt obtained may be converted, in the usual manner, into sodium formaldehyde sulphoxylate. (2) Ammonium sulphite is treated, in aqueous solution, at a temperature of 95°–100° C., with zinc dust and formaldehyde. Ammonia is evolved and zinc formaldehyde sulphoxylate is produced. (See also this J., 1905, 727 and 1300.)—E. B.

UNITED STATES PATENT.

Silk; Process of Bleaching Artificial ——. C. A. Ernst, Lansdowne, Pa., Assignor to S. W. Pettit, Philadelphia, Pa. U.S. Pat. 805,456, Nov. 28, 1905.

FILAMENTS of viscose "or similar material" are bleached

FRENCH PATENTS.

Dyestuffs; Production of New Nitroaliphylacidylaminonaphtholsulphonic Acids, Nitroaliphylaminocidylaminonaphtholsulphonic Acids, Aminoaliphylacidylaminonaphtholsulphonic Acids or Aminoaliphylaminocidylaminonaphtholsulphonic Acids and of New Azo — derived therefrom. Société pour l'Ind. Chim. à Bâle. Second Addition, dated May 20, 1905, to Fr. Pat. 321,640, May 31, 1902 (this J., 1903, 210; see also Eng. Pat. 13,778 of 1902; this J., 1902, 1374).

THE process of the main patent is altered by condensing 1,2-diaminonaphtholsulphonic acids, instead of aminonaphtholsulphonic acids, with nitroaliphyl acid chlorides. The substances obtained have the general formula $(\text{NH}_2)(\text{NH}.\text{CO}.\text{R}.\text{NO}_2)\text{C}_{10}\text{H}_5.\text{n}(\text{OH})(\text{SO}_3\text{H})_n$, and on reduction are converted into the corresponding aminoaliphylacidylaminonaphtholsulphonic acids. These substances, like other acidyl-o-dianilines have a strong tendency to separate a molecule of water, and they are isolated in the form of an inner anhydride.

The new dyestuffs claimed, are prepared (1) by combining these anhydrides with diazo- or tetrazo-bodies; (2) by further diazotising the dyestuffs so produced and combining them with amines or phenols either in substance or on the fibre; (3) by diazotising the anhydrides or the hydrated bases and combining them with amines or phenols, and then combining the monoazo dyestuffs thus obtained, with diazo- or tetrazo-bodies. The following examples are given:—(1) Anhydro-*m*-aminobenzoyl-1,2-diamino-5-hydroxynaphthalene-7-sulphonic acid is prepared by reducing the condensation product of 1,2-diamino-5-hydroxynaphthalene-7-sulphonic acid and *m*-nitrobenzoyl chloride. (2) This substance is combined with diazotised *m*-xylidine in a solution made alkaline with sodium carbonate. The reaction product is stated to dye un mordanted cotton in "blue" shades and to yield a bright scarlet of great fastness to washing after diazotisation and development on the fibre with β -naphthol. (3) Anhydro-*p*-aminobenzoyl-1,2-diamino-5-hydroxynaphthalenesulphonic acid is combined in alkaline solution with diazotised *p*-aminoacetanilide, and yields a bluish-red direct dyestuff, which may be diazotised and developed on the fibre to a bluish scarlet and to possess great fastness to washing. Other diazo-bodies may be employed, such as those of aniline, *o*- and *p*-toluidine, *p*-xylidine, *m*-phenylloxamic acid, α - and β -naphthylamine, dehydrothiolimidine, &c., or tetrazo-bodies, such as tetrazotised paradianilines, diaminoazoxybenzene, diaminoazobenzene, diaminoazophenylurea, &c. Other sulphonic acids of 1,2-diaminonaphthol, such as 1,2-diamino-5-hydroxynaphthalene-3,7-disulphonic acid, and also other nitro-aliphylacidyl chlorides may be used for preparing the condensation products, such as *o*- and *p*-nitrobenzoyl chloride, and methyl, halogen, or alkoxy derivatives of the nitrobenzoyl chlorides. Instead of the nitroaliphyl acid chlorides the corresponding acetaminosalicylic acid chlorides may be employed, and in this case the condensation products are hydrolysed with dilute mineral acids to obtain the required amino bodies or their anhydrides.—H. L.

Anthracene Derivatives and Dyestuffs [Anthracene Dyestuffs]; Production of a Series of New — and their Application in Dyeing and Printing. Badische Anilin und Soda Fabrik. Fifth Addition, dated June 22, 1905, to Fr. Pat. 349,531, Dec. 21, 1904. (See this J., 1905, 192, 726, 840, 841, 1010.) Under Int. Conv., Feb. 2, 1905.

IN addition to the substances already claimed, the homologues of the hydroxyanthraquinones, naphthanthraquinones and their reduction products and those of α -aminoanthraquinone may be condensed with glycerol or one of its anhydrides or esters or compound esters.—H. L.

Anthracene Derivatives and Dyestuffs [Anthracene Dyestuffs]; Production of a Series of New — and their Application in Dyeing and Printing. Badische Anilin und Soda Fahr. Sixth Addition, dated June 22, 1905, to Fr. Pat. 349,531 of Dec. 21, 1904. (See preceding abstract.) Under Int. Conv., April 14, 1905.

BENZANTHRONES are converted into new "vat" dyestuffs

for cotton by the action of alkali. Thus 10 kilos. of α -benzanthronequinoline (prepared from α -aminocanthraquinone) are mixed with 50 kilos. of caustic potash and 40 kilos. of absolute alcohol at 160° C., and gradually heated to 220°—230° C. with good stirring. After purification, a new product is obtained, which dyes cotton from a hydrosulphite vat in blue shades of great fastness.—H. L.

Indigo; Production of Leuco Derivatives of —. Deutsche Gold- und Silber-Scheide-Anstalt vorm. Roessler. Fr. Pat. 350,500, July 31, 1905. Under Int. Conv., Aug. 13, 1904.

A METHOD of producing leuco-derivatives of indigo by melting certain benzene derivatives, such as phenylglycine, with an alkali amide in presence of alkali hydroxide is already known. According to the present invention the alkali amide is partially or entirely replaced by alkali metal and relatively small amounts of alkali amide or ammonia. The ammonia forms alkali amide, this reacts with the benzene derivative, re-forming ammonia, and the cycle of reactions is repeated indefinitely. The necessary ammonia may be produced by initially adding to the melt some compound, such as urea, which decomposes and yields ammonia under the conditions present in the melt. The most satisfactory method of carrying out the reaction is to pass gaseous ammonia into a melt containing an alkali metal, alkali hydroxide, and a suitable benzene derivative. For example, 1000 grms. of a mixture of sodium and potassium hydroxides are melted in a closed vessel provided with a stirrer; after expelling the air by means of a current of gaseous ammonia, which is passed through the melt, 120 grms. of sodium are added, followed by 425 grms. of the potassium salt of phenylglycine in small quantities. During these operations a slow current of ammonia is maintained. The addition of the phenylglycine takes about 45 minutes. After it is all added the melt is still heated for a short time, in a gentle current of ammonia, until the reaction is completed. The most suitable temperature is 200° C., and about 20 litres of ammonia are introduced altogether. Prolonged contact of the final product with excess of alkali amide is disadvantageous.—E. F.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Wool, Goat Hair, and Camel Hair; Sorting, Willying, Washing, Combing and Carding —. Statutory Rules and Orders, 1905, No. 1293.

A PAMPHLET of regulations, dated Dec. 12, 1905, has been issued by the Secretary of State, relating to processes of sorting, willying, washing, combing and carding wool, goat hair and camel's hair and processes incidental thereto. The regulations came into effect on Jan. 1, 1906. [T.R.]

Wool Rugs; Dyeing and Dressing of —. J. W. Lamb. J. Soc. Dyers and Col., 1905, 21, 322—326.

Preparation of the Skins.—The skins are first sorted and cleansed from paint or tar marks with turpentine or naphtha.

Soaking and Washing.—After "trimming," the skins are "fleshed" over the beam, and then washed in water to remove blood and dirt. To prevent putrefaction, a little antiseptic should be added to the wash waters. Thorns, &c., are removed by the "burring" machine.

Scouring.—The skins are well scoured by hand, on both sides, with a strong solution of soft soap to which either sodium carbonate or ammonium carbonate is sometimes added. They are then rinsed in tepid water and the scouring repeated if necessary, the skins being finally hydro-extracted.

Leathering.—A mixture of aluminium sulphate or potash alum with common salt, is rubbed into the flesh side until the skin is fairly dry; after leaving over night the process is repeated. In some cases a tepid solution of

THE machine is said to combine large output with small dimensions. The bobbins 1 are each supported on two rollers 2. Three bands of wool, 3, 4 and 5, formed by the unwinding of three sets of bobbins, pass through guides, 6, over the cylinder, 7, again through guides, 8, between cylinders 9 and 10 and then over 11 and into the washing-bath, where they pass over rollers 13 to 17. They are then passed over roller 18 and pressed between rollers 19 and 20 and proceed to the folder. Roller 20 is covered with wool or felt, and is under pressure. Rollers 13, 15 and 17 are furrowed, and the bands of wool pass along the furrows. The various rollers are driven by suitable gearing.—E. F.

Thread on Bobbins: Treatment of — for Purposes of Dyeing, Bleaching, Washing, Degreasing, Mordanting and Impregnation: Method and Apparatus for —. H. Giesler. Fr. Pat. 356,371, July 24, 1905. Under Int. Conv., June 10, 1905.

THE bobbins are mounted on perforated spindles in the usual manner, but are traversed by the dye-liquor, under the influence of its own pressure only, from the outside to the inside, and away through the perforated spindle. It is claimed that by this means the liquor passes through the material at an exceptionally high rate of speed, and that for this reason, and also because the pressure exerted is very uniform and relatively very small, very uniform dyeings are obtained. From below the spindles the dye-liquor is pumped up to an open reservoir, where it is reheated to the required temperature, and from which it flows back continuously into the dye-vat. There are arrangements for keeping the liquor in the dye-vat at a constant level, which is varied according to the nature of the material to be dyed and the temperature of the vat. Under a pressure of 600 mm. of dye-liquor, when this is kept at the boil, 24 to 3 litres pass per minute through each bobbin holding 15 grms. of fine wool. In the case of coarse wool a column of 400—600 mm. only is required, in order to work at the same speed. If, on the contrary, extra-fine wool is to be treated (for example, 78,000 m. per kilo.), the column of liquid must be increased to 700 mm. to obtain the same rate of circulation. It is best to dye at 95°—100° C., but if lower temperatures are employed, the rate of circulation of the liquid decreases.—E. F.

Benzene Employed for Cleaning Textiles: Process and Apparatus for Recovery of the —. E. Delhotel. Third Addition, dated July 5, 1903, to Fr. Pat. 344,848, July 16, 1901 (this J., 1904, 1213; 1905, 130, 1189).

ACCORDING to the methods and apparatus described in the original patent, the drying oven can be opened and closed for the removal and entry of textiles under treatment without interruption of the process of recovering the benzene. Advantage is taken of this fact, according to the present addition, by the use of a drying oven, subdivided into many compartments, each of which can be opened and closed separately, and can be shut off, meanwhile, from communication with the other compartments. These compartments can be placed in communication in series, by means of pipes, in any desired sequence, so that the air which circulates, and finally returns to the condenser, may first pass over material from which almost all benzene has been removed, and finally over material fully charged with benzene, thus securing greater efficiency.—E. F.

Dye-vat. J. O. Obermaier. Fr. Pat. 356,187, July 17, 1905.

THE vat is intended for dyeing raw materials and threads. It is constructed of wood, and is divided into two portions by a vertical partition. Each portion has a perforated false bottom. The spaces below these communicate with a circulating pump by means of a four-way cock. The vat is closed above by a perforated lid, which rests on the top of the vertical partition. The dye-liquor is circulated, by the action of the pump, up through one compartment, down through the other, back to the pump, and so on. By means of the four-way cock the direction of circulation can be reversed. The dye-liquid may be pumped up into a storage tank by means of a separate pipe connected to the pump.—E. F.

Polychrome Printing; Imppts. in —. J. J. Hart. Fr. Pat. 356,153, July 13, 1905. Under Int. Conv., June 10, 1905.

BLOCKS of coloured composition loose polychrome printing have hitherto been made by mixing wax, fatty materials, soap, gelatin, or a similar substance with an insoluble substance, such as fullers' earth, kaolin, &c., and then adding to the composition so obtained the necessary colouring matter in the form of powder. When treated with solvents in the process of printing it is found that whilst the wax, &c., dissolves, the colouring matter of such blocks remains behind as an insoluble crust, to the detriment of the process. According to the present patent the colouring matter is dissolved in a suitable medium and this solution then mixed with fullers' earth or other insoluble material. The mixture is then slowly dried, and the dry, coloured mass so obtained is intimately mixed with the wax or other soluble ingredient. For example, 5 kilos. of 20 per cent. Alizarin paste are dissolved in 0.5 kilo. of ammonia solution of "880° Twaddell" and 2.5 litres of water, and then mixed with 0.5 kilo. of kaolin, fullers' earth, or some other suitable, insoluble substance. The mixture is filtered, dried, ground and mixed with 1 kilo. of a composition of wax, soap, gum or some other soluble substance. Colours soluble in fatty substances may be dissolved in the wax or other soluble composition, and then mixed directly with the fullers' earth or other insoluble substance. Suitable mordants may also be dissolved in solvents and mixed with the colouring matter in the kaolin or fullers' earth, and the mixture may then be employed for printing fabrics either with or without the help of the mordant ordinarily employed.—E. F.

Designs on Fabrics; Production of —. C. W. Fulton. Fr. Pat. 356,188, July 17, 1905.

FAUCES consisting of two or more materials are printed, from an ordinary printing roller, with chemicals which destroy one of the materials of the fabric. The chemicals employed may at the same time change the colour or shade of the undestroyed fabric at the points at which they are applied. If the fabric is made of one material only, part of this, for instance, the warp or the weft only, may be previously coated with a substance which resists the action of the chemical employed. If, in such a case, the warp and weft are coloured differently, a two-coloured effect is thus obtained. From fabrics containing wool and cotton the latter may be removed in places by application of aluminium chloride, followed by the application of a dry heat and removal of attacked cotton by friction. Similar results can be obtained in a fabric composed of threads of wool and silk by the help of alkali hydroxide.—E. F.

Drying Chamber; New — for Sizing, employing a Current of Hot Air. J. Caquelin. Fr. Pat. 356,579, Aug. 1, 1905.

IN this apparatus direct heating of the thread which is to be dried, otherwise than by means of a current of hot air, is avoided. The speed [of the current of air] can be regulated at will by the operator, who can also stop or start it instantaneously. The air is heated by means of hot pipes in a separate chamber from which it enters the drying chamber, which contains a number of vertical partitions open at top and bottom alternately. The hot air and the thread traverse this chamber in opposite directions, the intensity of the air-current being regulated by means of a valve.—E. F.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

ENGLISH PATENT.

Printing on Leather. M. C. Lamb, Blackheath, Kent, and J. D. G. Kennie, London. Eng. Pat. 17,338, Aug. 28, 1905.

A SUITABLE dyestuff or colour base is dissolved in benzene

or oil of turpentine, and the solution thickened with petroleum jelly, &c. The design to be reproduced on leather is painted or printed on paper or calico or other suitable medium by means of the above preparation. When dry, the transfer is laid upon leather, and the whole pressed with hot irons or passed under hot rollers, whereby the design is transferred to the leather.—T. F. B.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

Iron Carbonyl; Physical and Chemical Properties of
—, Su J. Dewar and H. O. Jones. Roy. Soc. Proc.,
1905, 76A, 558--577.

The authors have prepared iron carbonyl in a pure state as a yellow liquid boiling at 102.7° C. under 764 mm., and have carried out analyses which show it to have the formula $\text{Fe}(\text{CO})_5$. It is more stable towards such reagents as the halogens, iodine chloride, &c., than nickel carbonyl, and it is not attacked by hydrochloric acid, hydrobromic acid, a solution of sulphur in carbon bisulphide, nitric oxide, or sulphuretted hydrogen. Nitric and sulphuric acids, however, rapidly attack it, in the latter case the action being more vigorous than with nickel carbonyl. When heated with benzene and aluminium chloride in a sealed tube at 100° C., benzaldehyde and aniline are produced. In direct sunlight it is slowly transformed into a solid compound having the formula $\text{Fe}_2(\text{CO})_9$. This reaction is more complete, and a purer product is obtained, if the iron pentacarbonyl is in solution in absolute ether, in which the resulting compound is sparingly soluble.

Diferro-nona-carbonyl, $\text{Fe}_2(\text{CO})_9$, decomposes at 100° C. with formation of iron, carbon monoxide, and iron pentacarbonyl. Under certain circumstances the above reactions can be made reversible. Thus, tubes containing iron carbonyl alone or in solution, may be left exposed to light till separation of solid takes place, and then, if allowed to stand at the ordinary temperature in the dark for some weeks, the solid is found to have disappeared. When a solution of iron carbonyl in nickel carbonyl—which is much paler in colour than a corresponding solution in ether—is allowed to stand in sunlight, no precipitation occurs unless the solution is concentrated, although with a moderately concentrated solution, separation of solid in the vapour space above the liquid takes place. The author shows that this is not due to the absorption of light by the nickel carbonyl, and suggests that an intermediate double compound, $\text{FeNi}(\text{CO})_9$, which does not separate, is formed.—B. J. S.

Chlorine; Determination of Density of —, F. P. Treadwell and W. A. K. Christie. Z. angew. Chem., 1905, 18, 1934—1935.

CALCULATIONS of the volume of chlorine from its weight are rendered uncertain because there are no trustworthy determinations of the density of chlorine at ordinary temperatures, and chlorine, being at ordinary temperatures a vapour, not a perfect gas, does not follow Boyle's law with accuracy. The authors have made determinations, by weighing against one another two similar bulbs of about 400 c.c. capacity, each provided with two stop-cocks for entry and exit of gas. The capacity of these was accurately determined, and the two were counterpoised after being filled with air at ascertained temperature and pressure. One was then filled with chlorine, and the increase of weight determined; the chlorine was then absorbed by freshly-boiled solution of sodium hydroxide, and the remaining air carefully measured. All the data were thus obtained for calculating the density. The densities thus determined were 2.488 at 20° C. and 730 mm., 2.489 at 10° C. and 725 mm., compared in each case with air at the same temperature and pressure. Calculating by Boyle's and Gay Lussac's laws to N.T.P., the volume of 0.003545 gram. of chlorine, equivalent to 1 c.c. of N/10 solution, works out to 1.1021 and 1.1015 c.c. respectively; by which is meant, not that either of these figures is the volume of that weight of chlorine at N.T.P., but that correction of these volumes by Boyle's and Gay Lussac's laws to 20° and 10° C. respectively, and to pressures not greatly differing from 760 mm. will give the true volume of 0.003545 gram. of chlorine at those temperatures and pressures.—J. T. D.

Borax Production of the United States. Mining World, Dec. 2, 1905.

ALL the output of borax in the United States continues to come from California, and the larger proportion from the extensive colemanite deposits in San Bernardino county. The total production for the year 1904 amounted to 45,647 tons of the crude material, valued at 698,810 dols. Of this amount 38,000 tons, valued at 508,000 dols., came from San Bernardino county, Cal., the remainder coming from Ventura and Inyo counties. In 1903 the returns gave an aggregate production of crude borax amounting to 34,430 short tons, valued at 461,400 dols. The production in 1902 was 14,700 short tons of refined borax, valued at 2,447,614 dols., of which 862 short tons, valued at 150,000 dols., were stated to be boric acid, and 2600 short tons of crude borax, valued at 41,000 dols., a total of 20,004 short tons, valued at 2,538,614 dols. [T.R.]

Nitrate of Soda Statistics. W. Montgomery & Co. Dec. 30, 1905.

Furnace Gases; Re-heater for —. [Contact Process for Sulphuric Acid.] H. Howard, Brookline, Mass. U.S. Pat. 801,318, Oct. 10, 1905.

This invention relates to the re-heating of furnace-gases obtained in the manufacture of sulphuric acid by the contact process, after these gases have become cooled in the process of purification. In the rear wall of the re-heating chambers is arranged a re-heating chamber divided into a number of deep pockets in which are placed re-heating units, in the form of U-shaped pipes. In a longitudinal chamber above the pockets are two parallel conduits, one of which conducts the cooled gases from the purifier to the re-heating units, which are connected with it in parallel, while the other conduit conducts the re-heated gases from re-heating units to the "contact" chamber. The re-heating units are heated by conduction through the walls of the furnace, without direct contact with the mass of roasting ore. The independent units of the re-heating coils are connected in series with one another, and for ease of repair, &c., are connected with the conduits by means of detachable couplings. The longitudinal chamber containing the conduits is formed by the upper open ends of the pockets.—W. C. H.

Sulphur; Process of Recovering —. R. Baggeley, Pittsburg, Pa. U.S. Pat. 805,701, Nov. 28, 1905.

The process consists in continuously "passing sulphur-bearing fumes from a smelting furnace through a travelling combustible screen of waste material and depositing sulphur thereon, and then burning the screen and subliming and collecting the sulphur.—E. S.

FRENCH PATENTS.

Seaweed; Treatment of — for the Extraction of Mineral and Organic Chemical Matters. Mme. Laureau, née J. H. Laureau. Second Addition, dated Aug. 7, 1905, to Fr. Pat. 352,089 of March 6, 1905 (this J., 1905, 892) [First Addition, dated May 24, 1905; this J., 1905, 1172.]

SEAWEED is treated with acids and hydrocarbons, either before, or simultaneously with a treatment with milk of lime. The hydrocarbons proposed are coal tar, benzene (petroleum spirit), or heavy oils, with or without water. The acid solutions are treated with ordinary reagents to extract the iodine.—E. S.

Hydrogen Peroxide [Solutions]; Stable —. W. Heinrici. Fr. Pat. 356,880, Aug. 8, 1905.

THIS invention relates to a process for preserving dilute solutions of hydrogen peroxide, and consists in the addition to them of small quantities of neutral organic compounds that may be regarded as derivatives of ammonia, such as amides, imides, acetyl derivatives of aromatic bases, and derivatives of urea.—W. C. H.

Carbon Dioxide; Manufacture or Recovery of —. J. C. Stead. Fr. Pat. 357,163, Aug. 24, 1905. Under Int. Conv., Aug. 30, 1904.

GERMAN PATENTS.

Caustic Alkalis or Alkali Carbonates; Process for the Manufacture of — by the Action of Quicklime or Calcium Carbonate on Alkali Silicofluorides, with Recovery of the Hydrofluosilicic Acids from the Residues. J. A. Reich. Ger. Pat. 161,796, March 14, 1903.

THE manufacture of alkalis by the action of quicklime or calcium carbonate on alkali silicofluorides, according to either of the following equations: (a) $\text{Na}_2\text{SiF}_6 + 4\text{CaO} = \text{Na}_2\text{O} + 3\text{CaF}_2 + \text{CaSiO}_3$, or, (b) $\text{Na}_2\text{SiF}_6 + 4\text{CaCO}_3 = \text{Na}_2\text{CO}_3 + 3\text{CaF}_2 + \text{CaSiO}_3 + 3\text{CO}_2$, has not proved successful in practice, since it has not been possible to recover economically the hydrofluosilicic acid from the residues, these latter being only incompletely soluble in hydrochloric acid, very difficult to wash, and giving varying and incomplete yields of hydrofluosilicic acid. To avoid these difficulties, the patentee proposes to intimately mix the residues with a much larger quantity of lime, for example with a quantity of lime (in the form of quicklime, slaked lime or milk of lime) equal to that which was required for the complete decomposition of the alkali silicofluoride. This excess of lime is preferably added before or during the decomposition of the alkali silicofluoride; that is, in mixing the charge, twice the necessary quantity of lime is taken. The above method is for use in order to obtain almost theoretical yields, but, in practice, it would probably be better, in order to reduce the quantity of hydrochloric acid needed for working up the residue, to use about nine parts of lime to five parts of alkali silicofluoride.—A. S.

Alkaline-Earth Sulphides; Process for Obtaining Chlorides and Sulphur from Sulphur Chloride from —. Konsortium f. Elektrochem. Ind., G.m.b.H. Ger. Pat. 162,913, Feb. 23, 1904.

ALKALINE-earth sulphides are converted into chlorides by the action of chlorine, sulphur or sulphur chloride being also formed. The sulphur formed in the first stage of the reaction reacts with the unattacked sulphide to form polysulphide, which is in turn chlorinated, with separation of sulphur. The first stage of the reaction, which may be represented by the equation: $5\text{BaS} + 4\text{Cl}_2 = \text{BaS}_2 + 4\text{BaCl}_2$, proceeds violently and is often accompanied by incandescence, but the second stage: $\text{BaS}_2 + \text{Cl}_2 = \text{BaCl}_2 + \text{S}$ goes on very slowly. It is now found that the chlorination of the polysulphides (and also monosulphides) can be easily effected by treating them in aqueous solution with sulphur chloride. According to the present patent, therefore, the alkaline-earth sulphide is heated in a current of chlorine until the chlorine present in the distillate, in the form of sulphur chloride, is sufficient for the complete chlorination of the sulphides in the residue. The cooled residue is then dissolved in water, and treated with the distillate consisting of sulphur chloride. The reactions proceed according to the equations: $\text{BaS} + \text{S}_2\text{Cl}_2 = \text{BaCl}_2 + \text{S}$; $\text{BaS}_2 + \text{S}_2\text{Cl}_2 = \text{BaCl}_2 + \text{S}$. If it is desired to obtain finally some of the sulphur in the form of sulphur chloride, the dry chlorination is carried on for a longer time.—A. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

Ceramic Wares: Production of Metallic Lustre and Iridescence on the Surface of ———. 1. Frauchet. *Comptes rend.*, 1905, 141, 1020-1022.

THE author's plan consists in incorporating metallic salts in a powdered glaze which will melt at the baking temperature of the ware to be treated, and then exposing to a reducing atmosphere. The foundation of the glaze consists of: quartz, 12; *pegmatite*, 12.5; kaolin (*Eyzies*), 2; sand (*Decize*), 20; red lead, 30; borax, 19.2; boric acid, 2; potassium carbonate, 2; sodium chloride, 1.8; this mixture is powdered, melted, poured into water, and ground. To glaze the ware, one or other of the following formulae is used, the above mixture being called A:—

	1.	2	3
Glaze A	100	100	100
Kaolin	10	10	10
Silver carbonate	2	0.5	2
Zinc oxide	—	1	—
Stannous oxide	—	1	—
Bismuth sub-nitrate	—	—	4
Copper oxide	—	3	—
Copper carbonate	—	—	1

The glaze is applied in the usual way (the proportion of kaolin having been reduced or increased if the glaze is to be made more or less readily fusible), and the ware baked in a muffle, the furnace of which can be completely closed. When the baking is complete, the whole is allowed to cool to dull redness, the damper shut, and either: (a) Brushwood, wood, coal, resin, oil, tar, or other combustible introduced into the fire, so as to produce a dense smoke which penetrates into the muffle, and the smoke allowed to act, with the furnace closed, for an hour; or (b), coal-gas is introduced by tubes into the muffle, say at 3 cb.m. per hour, for a muffle of 0.5 cb.m. content. The reduction is complete in 10 minutes, and the exposure should not exceed 30 minutes. The same result may be obtained, though not so well, by (c). Combustion of sugar or similar substances instead of those mentioned in (a). The method (b) has the advantage that the process can be watched; and with silver, the tint can be varied from white to gold according to the duration of the process. Copper gives its own colour, but with the addition of bismuth, a blue pearly effect is obtained. Formulae 1 and 3 mixed give a brilliant metallic green. All the colours show better on a matt than on a highly glazed surface. —J. T. D.

Pottery Imports into the United States. Mining World, Dec. 2, 1905.

THE imports of pottery into the United States in 1904 were valued at 11,270,241 dols., and the production at 25,158,270 dols. — a total of 36,428,511 dols. After deducting the exports, there appears a net consumption of 35,604,132 dols., of which the domestic production was 70.66 per cent. in 1904, as compared with 70.56 per cent. in 1903, 72.91 per cent. in 1902, 71.39 in 1901, 70.75 in 1900, 69.99 in 1899, and 68.49 in 1898. It will thus be seen that the gradual increase of domestic production as compared with consumption from 1898 to 1902 was checked in 1903 by a fall from 72.91 to 70.56 per cent.; in other words, domestic production did not increase as rapidly as importation. [T.R.]

ENGLISH PATENT.

Enamelled Metal Objects; Machine for the Producing of Coloured Ornamentations on ———. I. Gaensler, Turin, Italy. Eng. Pat. 19,080, Sept. 21, 1905.

ON the surface of a horizontal drum, capable of being rotated at varying speeds, are mounted a number of rings,

to which are loosely connected a number of wires of the same length but having differently shaped ends. During the rotation of the drum, the centrifugal force causes these wires to fly out from the drum, and to dip into a reservoir containing fluid enamel at the bottom, which is then sprinkled in the form of a spray over the enamelled metallic objects to be decorated. By pushing the metal objects against the wires, whilst the enamel is still fluid, spots with only very fine veinings in between may be obtained. The reservoir at the bottom of the drum may be divided into any number of compartments, corresponding to partitions on the drum, and the objects may thus be treated with differently coloured enamels by the same drum. —A. G. L.

UNITED STATES PATENTS.

Glass Tile, Slab, or the like. C. H. Thompson, Stonor-bridge. Assignor to Maw and Co., Jackfield, England. U.S. Pat. 805,595, Nov. 28, 1905.

THE claims include the improved tile produced by the following process:—"Keys" of silicous or granular material are fixed to the back of the tile by applying to it a solution of a double silicofluoride, which after dehydration is insoluble in water; on this coat pieces of silicous material are sprinkled; the whole is then dried, and warmed without fusing the silicofluoride and gradually cooled. For the backing coat a solution in liquid sodium silicate of a double fluoride of sodium and aluminium, calcined dolomite, sodium fluoride, and kaolin, is suggested. The adhesion of the coating to the slab is said to be increased by the roughening of the surface of the slab, caused by the action of the fluorine from the coating when the latter is heated to a point below the fusing-point of the silicofluoride. —W. C. H.

Glass Plates; Manufacture of ———. B. C. White, Mosgrove, Pa. U.S. Pat. 805,609, Nov. 28, 1905.

THE method described of making glass plates consists in forming two or more glass sheets, which are deposited in succession, one upon a supporting surface and the other upon the first sheet; between these a metallic web or fabric may be interposed, and the sheets compressed by means of a roller. The claims also include a machine for carrying out this process, which consists of a combination of two or more pairs of rolls, each pair being arranged to form a sheet, with a bed or platen to receive the sheets formed. Either the pairs of rolls or the bed are movable relative to each other. The pairs of rolls are arranged to deposit the sheets of glass in succession on the bed, or on the previously formed sheet or sheets. Means are also provided for interposing a metallic web or fabric between successive sheets, and for compressing the sheets by means of a roll. —W. C. H.

Glass Plates; Manufacture of ———. B. C. White, Mosgrove, Pa. U.S. Pat. 805,610, Nov. 28, 1905.

THIS method of making glass plates consists in forming and laying a glass sheet upon a suitable surface, and then reversing the direction of the distributing device, that is, without disruption, depositing a second sheet upon the first, the resulting plate being composed of a sheet doubled upon itself. Between the sheets a metallic web or fabric may be interposed, and the sheets, or the sheets and metallic web, may be compressed by a pressure mill. The apparatus described includes a means of forming glass sheets, e.g., a pair of rolls, and a support for the sheets formed, means being provided for imparting a backward and forward movement, either to the arrangement for forming the sheets or to the bed, for placing a metallic web or fabric on the first sheet formed, and for compressing the layers. —W. C. H.

Glass Sheets; Manufacture of ———. J. H. Lubbers, Allegheny, and S. L. Bodine, Berwyn, Assignors to Window Glass Machine Co., Pittsburgh. U.S. Pat. 807,298, Dec. 12, 1905.

SEE Eng. Pat. 22,065 of 1904; this J., 1905, 29. —T. F. H.

FRENCH PATENT.

Enamelling Iron Objects; Process for — R. F. Wagner.
Fr. Pat. 356,736, Aug. 7, 1905.

THIS process for enamelling iron objects is based on the employment of an alkaline-earth phosphate, in order to increase the refractory properties of the enamel and to render it opaque. Mixtures of enamels containing phosphoric acid with enamels containing alkaline-earth compounds are baked in order to bring about the formation of alkaline-earth phosphates during the baking.—W. C. H.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

ENGLISH PATENTS.

Roads and Streets; Method for Preserving and Improving the Surfaces of Macadamised — and Preventing the Formation of Dust resulting from the Disintegration of Macadamised Surfaces. E. D. de Liebluber, Wembley Hill. Eng. Pat. 16,400, July 25, 1904.

SEE Fr. Pat. 356,330 of 1905; this J., 1905, 1307. — T.F.B.

Wood; Process of Preparing — for Polishing Purposes. O. Bohne and J. G. Hermann, Dresden, Germany.
Eng. Pat. 9496, May 5, 1905.

A mixture of an insoluble mineral substance with an organic binding material and a small quantity of potassium bichromate is rubbed into the pores of the wood. The superfluous powder is then removed with a dry cloth and the surface of the wood treated as usual with shellac dissolved in 80 per cent. alcohol. Suitable compositions are: For wood with large pores, e.g., rose wood, 75 parts of plaster of Paris, brick dust, clay, &c.; 25 parts of animal or vegetable glue, or dextrin; and five parts of potassium bichromate. For wood with fine pores, e.g., walnut, 80 parts of the mineral matter, 20 parts of the binding material, and five parts of potassium bichromate. By adding brick dust, &c., the colour of the filling material is suited to that of the wood.—A. G. L.

UNITED STATES PATENTS.

Bricks, Tiles, and other Articles; Apparatus for Producing Nitrided — R. Bagnaley, Pittsburg, Pa.
U.S. Pat., 805,702, Nov. 28, 1905.

MOLTEN slag is fed into moulds carried by a travelling endless chain; covers for the moulds are also arranged "in travelling series," each cover having in its middle a plunger for shaping the article to be formed, and being of "greater gravity than the pressure to be applied to the plunger." After the articles in the moulds have set, they are delivered by suitable conveying mechanism, into an annealing chamber. Before passing into the annealing chamber, a protective coating may be applied to the articles to prevent them from being cooled too rapidly.—E. S.

Kiln; Cement-Burning — G. D. Helmick, Fort Russell, Wyo. U.S. Pat. 805,953, Nov. 28, 1905.

By this invention the combination is claimed of one or more burning furnaces, with one or more regenerators arranged below the furnaces. A spirally-descending flue connects the furnaces with the regenerators, and controlling means are arranged between it and the regenerators. On the peripheral surface of this flue one or more apertures are arranged, and adjacent to these are dust-collecting boxes, having slanting floors, and exit openings. Between

the regenerators and the furnaces are arranged independent flue connections, outside the spiral flue, for returning the heated air to the material being treated.—W. C. H.

Cement; Process for Manufacturing Portland — E. H. Hurry, Bethlehem, and H. J. Seaman, Catawauqua, Pa. U.S. Pat. 806,146, Dec. 5, 1905.

SEE Eng. Pat. 10,958 of 1901; this J., 1902, 1079.—T.F.B.

FRENCH PATENTS.

Kilns for Burning Bricks. A. A. Gery. Fr. Pat. 356,838, June 27, 1905.

THE kiln consists of one or more long channels through which the articles to be burned are conveyed, on carriages, from one end to the other, and pass successively through the processes of drying, heating, burning, and cooling. In starting the kiln, a "grate-carriage" is required, provided with a vertical refractory wall which just fits the channel, and has a heating opening in it. The middle portion of the length of the kiln forms the burning zone, and is provided with a series of suitably spaced openings for the supply of the combustible body. The fore-part of the channel serves for drying the bricks introduced and is provided with a chimney, by which a current of air is maintained through the channel in the opposite direction to that in which the carriages move. This current is controlled by two series of vertical dampers, one before and one behind the burning zone; the dampers can be adjusted to varying heights above the line of the floors of the carriages, and when inserted to a considerable depth, cause the air to pass to the bottom of the piles of bricks. A second chimney is provided further along the drying zone just in front of an additional damper, to ensure the removal of the moisture and prevent condensation on the bricks. The lateral walls of the channels in the fore-part of the kiln, have deep longitudinal grooves, into which the moisture escapes through openings from the main channels, the deep grooves being controlled by plugs at the top, where they pass into a flue which communicates with the evaporation chimney. The invention includes the improved process of burning bricks, &c., which consists in loading the kiln with unburnt bricks on carriages end to end, causing a current of air to pass in the opposite direction through the kiln, heating the air that enters, combining this with the products of combustion before it comes in contact with bricks which are advanced, in order to heat these just to incandescence; the combustible is supplied to the bricks thus heated, and combustion is maintained by the previously mentioned current of air, which is heated by the burnt bricks as they pass to the rear end of the kiln. The bricks are burned by direct contact with the combustible, and the bricks that enter are dried by indirect contact with the combustible.—W. C. H.

Agglomerate for Constructional and Public Works. V. Labour. Fr. Pat. 356,901. Aug. 12, 1905.

THE compounded material described is made by agglomerating crystalline or amorphous carborundum with some binding agent used in constructional work, such as the various kinds of cement, "fat" or hydraulic lime, asphalt, &c.—W. C. H.

Wood; Process for Obtaining Artificially the Colour which — acquires with Age. R. Kornmann. Fr. Pat. 357,083, Aug. 21, 1905. Under Int. Conv., Aug. 22, 1904.

X.—METALLURGY.

Iron-Nickel-Manganese-Carbon Alloys, H. C. H. Carpenter, R. A. Hadfield, and P. Longmuir. Seventh Report to the Alloys Research Committee. Engineering, 1905, 708—713; 745—750; 779—784.

The alloys examined, contained the proportions of nickel, carbon and manganese shown in the following table:—

Mark.	Nickel.	Carbon.	Manganese
	Per cent.	Per cent.	Per cent.
A	nil	0.47	0.85
B	1.20	0.48	0.79
C	2.15	0.44	0.83
D	4.25	0.40	0.82
E	4.95	0.42	1.03
F	6.42	0.52	0.92
G	7.95	0.43	0.79
H	12.22	0.41	0.85
J	15.98	0.45	0.83
K	19.91	0.41	0.96

They were prepared with Swedish charcoal iron of special purity, this being melted along with the necessary ingredients, nickel and Swedish white iron. The mechanical tests were carried out on test pieces prepared from the alloys after the latter had been heated to 800° C. This temperature is well above the critical ranges of the alloys and was therefore selected as the most suitable for "normalising" the alloys.

Mechanical Tests of the Forged Alloys.—The results of the different mechanical tests show that with increase of nickel from nil up to 4 per cent., the effect on the mechanical properties is gradual. The alloys when under elastic stress yield more to the stress, but after the apparent yield point is passed, the maximum (tensile) stress increases. In nearly all the tests, there was a more or less pronounced kink in the curves between 0 and 4 per cent. of nickel. Between 4.25 per cent. and 4.95 per cent. of nickel, there is a very sudden change in nearly all the properties of the alloys, as is shown by a rapid increase of the maximum stress (reaching its highest value in the alloy containing 6.42 per cent. of nickel), a reduction of ductility and an increase of brittleness. Thus, for industrial nickel-iron alloys, there is a "change limit for nickel content" at 4½ per cent., when carbon and manganese are present to the extent of 0.44 and 0.88 per cent. respectively. After this sudden "break," the mechanical properties again change more gradually as the percentage of nickel rises, until about 16 per cent. is present; the brittle zone thus extends from about 5 to 15 per cent. of nickel. With still further increase, the change in properties is more rapid, and in the reverse direction to the preceding rapid change. Fig. 1, which shows the results

of the bending tests is roughly typical of the other curves representing the mechanical properties of the alloys. It is pointed out that the alloy K, containing 19.91 per cent. of nickel had the lowest yield point, and the highest elongation and reduction of area of all the alloys.

Mechanical Properties of the Cast Alloys.—The results obtained agreed generally with those given by the forged alloys, but the maximum tensile strength was shown by the alloy containing 7.95 per cent. of nickel. The three alloys F, G, H, which in the forged condition are distinctly brittle, show, in the cast "normalised" state, elongations of 6.2, 4.5 and 6.2 per cent. respectively.

Physical Chemical and Metallographical Properties.—The curves representing the electrical resistivity of the alloys afford additional evidence of the sudden change in the properties of the alloys when the proportion of nickel reaches about 4.25 per cent. The results of the magnetic tests show how closely the magnetic permeability is related to the structure of the alloy. In Fig. 2, the results

of the magnetic tests are given, together with the structure of the alloys. Determinations were also made of the amount of corrosion of the alloys at the ordinary temperature in well-aerated fresh water, in sea-water, and in 50 per cent. sulphuric acid. The test-pieces of metal weighed 70—80 grms.; the fresh water was renewed every day, and the sea-water once a week. The results are shown in Fig. 3.

The critical temperatures of the alloys on rising temperatures (heating curves) and falling temperatures (cooling curves) are shown in the following table, alloys Nos. 1 and 9 being included for the purpose of showing the effects of carbon and manganese respectively:—

Mark.	Percentages.			Critical Ranges on Cooling.	Critical Ranges on Heating.
	Nickel.	Carbon.	Manganese.		
1*	nil	0.01	trace	900-754° C. (1652-1389° F.)	
9*	"	0.47	"	770-688° C. (1418-1270° F.)	
A	"	0.47	0.05	Temperature steady at 695° C. (1274° F.)	729-755° C. (1344-1391° F.)
B	1.20	0.48	0.79	Temperature steady at 665° C. (1220° F.)	700-721° C. (1292-1330° F.)
C	2.15	0.44	0.83	687-646° C. (1268-1195° F.)	700-721° C. (1292-1330° F.)

* Journal of the Iron and Steel Institute, 1904, No. 1, Table II., pages 232 and 233.

The metallography of the alloys was also studied and a series of photo-micrographs is given. In the case of alloy K, which was the most suitable one for the purpose, the effect of mechanical treatment on the structure was studied more fully. In the untreated state, this alloy consists of large polyhedra, but mechanical work of various kinds, which stresses it beyond the elastic limit, causes an entirely new type of structure to appear. The polyhedra even after prolonged etching always appear white, whereas the new structural element invariably appears dark after etching. Further, the change of structure is accompanied by the appearance of magnetism. It was found that this new structure induced by (a) forging, (b) bending, and (c) compressing, which deformed the test-bars, without fracturing them, can be removed, and the original structure regenerated by a short heat treatment at 800°-900° C. The structural changes produced by stresses which caused fracture, are not as easy to remove, but by the treatment mentioned, there was an appreciable reversion, in parts, towards the original polyhedral structure, and it is probable that the restoration would be rendered complete by prolonged heat treatment at about 900° C. These results are not in agreement with those of Guillet, who stated that a steel which has once been changed from the polyhedral to the martensitic condition, by whatever method, cannot be regenerated either by annealing or quenching. (See this J., 1890, 905; 1898, 670; 1899, 48, 278, 687; 1900, 150; 1902, 485; 1903, 149, 213, 300, 423; 869, 911, 993.)—A. S.

Iron-Carbon Alloys; Diagram of Equilibrium of— G. Charpy. Comptes rend., 1905, 141, 948-951.

The author has examined the effects of slow and rapid cooling on the same alloy. He finds that if but little silicon or manganese be present, separation of graphite is never observed unless the total carbon be over 2 per cent. An alloy with 2.9 per cent. of carbon showed no graphite when poured into a metal mould, but when allowed to cool slowly in the crucible, showed 2.21 per cent. of graphite; when slowly cooled to 1100° C. and then rapidly cooled by plunging the crucible into water, the graphite was 0.95 per cent. It seems that at the beginning of solidification, mixed crystals separate, and this goes on till a eutectic of mixed crystals and cementite, or mixed crystals and graphite, is formed. This is the condition of alloys cooled rapidly after complete solidification; but if the cooling be slow, the mixed crystals disappear, cementite or graphite separating above 700° C., and pearlite below that temperature. The solidification of the cementite eutectic begins at 1150° C., not 1050° C., that of the graphite-eutectic about 10°-15° higher; and one

or the other is formed according to the conditions (especially the rate) of the cooling, but never both successively.
—J. T. D.

Iron and Steel Production in 1904. Eng. and Mining J., Dec. 2, 1905.

THE production of both pig-iron and steel was smaller in 1904, that of pig-iron being 2.2 per cent. less, and that of steel 0.4 per cent. less than in 1903. The ratio of steel to pig-iron production increased slightly, from 0.77 in 1903 to 0.79 last year. The decrease, both in iron and steel output, in 1904 was in great part due to the smaller make in the United States.

Steel Production of the World—Metric Tons.

Sweden	508,825	528,525
All others	626,000	633,000
Total	47,113,730	46,668,751

There is little change in relative rank in the two years. The three chief producers—the United States, Germany and Great Britain—furnished 77.2 per cent. of the world's

pig iron, and 76.9 per cent. of the steel last year. The United States alone made 36.4 per cent. of the pig iron, and 38.3 per cent. of the total steel. [T.R.]

Gold; Solubility of — in Thiosulphates and Thiocyanates. H. A. White. J. Chem. Metall. and Min. Soc. of S. Africa, 1905, 8, 109-111.

SOLUTIONS of sodium thiosulphate, sodium sulphide, ammonium thiocyanate, ferric sulphate, or ferric chloride, separately, and in the cold, are practically without action on gold (a boiling solution of ferric chloride readily dissolves gold); but sodium thiosulphate and ferric chloride together dissolve it, and the action of ammonium thiocyanate and ferric chloride together is still more marked. Other oxidising agents added to the thiocyanate are also effective, but none more so than ferric salts. Experiments in which gold was suspended in these liquids for some days showed that the action gradually slackened, no doubt from the conversion of ferric into ferrous salt and the consequent lack of oxygen. The presence of ferric salts from oxidation of pyrites, and the formation of thiocyanates from cyanides, no doubt account for the flow of gold from dumps, and the enrichment of the soil below the heap, which have been frequently observed. By means of a process founded on this action of thiocyanates, it may be possible to recover considerable quantities of gold from old residue heaps. —J. T. D.

Platinum; Solubility of — in Sulphuric Acid. M. Delépine. Comptes rend., 1905, 141, 1063-1015.

THE rapidity with which concentrated sulphuric acid attacks platinum (this J., 1905, 1302) varies greatly with the conditions of experiment. When the concentrated acid is boiled with platinum foil in a flask (338° C.), it turns distinctly yellow in half an hour, and the platinum dissolves at the rate of about 0.01 gram. per sq. decim. per hour. In a basin or other open vessel the attack is much slower, because the temperature is kept down by evaporation. In mixtures of 50 grams of sulphuric acid with 10 grams and 20 grams of potassium sulphate, which boil respectively at 350°-355° and 365°-370° C., the rates of attack are 0.04-0.05 and 0.12-0.13 gram. per sq. decim. per hour respectively. Traces of nitric acid, up to 0.1 per cent., added to pure sulphuric acid, do not sensibly affect the rate of attack, so that the attack of platinum by ordinary "commercially pure" sulphuric acid is not to be attributed to the traces of nitric acid which it may contain. Ammonium sulphate exercises a marked retarding influence; indeed, if to a sulphuric acid solution of platinum, ammonium sulphate be added, and the solution boiled, practically the whole of the platinum is precipitated, and no more is found in solution until the whole of the ammonium salt is destroyed. Spongy platinum is dissolved more rapidly by sulphuric acid than the compact metal, but the difference is probably one of surface only, and not due to any allotropic difference. The reaction of sulphuric acid on platinum is represented by the equation $4H_2SO_4 + Pt = Pt(SO_4)_2 + 2SO_2 + 4H_2O$; a platinum sulphate being formed. —J. T. D.

Copper Smelting; Constitution of Mattes produced in —. A. Gibb and R. C. Phelp. Trans. Amer. Inst. Min. Eng., 1905, Nov., 1193-1209.

THE mattes produced in modern copper-smelting vary in copper-content from 20 to 80 per cent., but mostly contain about 50 per cent. The amounts of arsenic, antimony, &c., contained in them are usually so small that they may be looked on as impurities simply, the essential constituents being copper, iron, and sulphur. In modern practice, where the work is done in a blast-furnace, the furnace atmosphere is oxidising, and no reduction of iron occurs. Names are given to the mattes according to their appearance:—"Coarse metal," with 35-55 per cent. of copper, hard, compact, dull bronze-colour, no visible metallic copper; "Blue metal," 60-70 per cent., bluish purple, with visible "moss copper"; "white metal," 70-76 per cent., white, unevenly plated appearance, usually homogeneous; 78-81 per cent., various names (e.g., "pinple metal," "close regule," "spongy regule," &c., according to appearance), show metallic copper in considerable proportion.

The authors find that, after determining the ultimate composition of a matte, its proximate constitution can in most cases be determined by the reaction upon it of solution of silver nitrate, from which metallic copper separates silver, cuprous sulphide, silver and silver sulphide, cuprous oxide, silver and basic copper nitrate, while ferrous sulphide is without action upon it, and iron acts so slowly that its reaction in any short time is negligible. Aided by this mode of analysis, they find that:—(1) Cuprous sulphide is the only compound of copper and sulphur stable in the melted condition; it will dissolve neither copper nor sulphur; (2) Ferrous sulphide is the only stable compound of iron and sulphur; it will take up no more sulphur, but much more iron, which, however, forms on cooling a solid solution, and not a compound; (3) Iron will decompose cuprous sulphide, and the action is reversible, equilibrium occurring when the mixture contains about 30 per cent. of ferrous sulphide; (4) Ferrous sulphide dissolves large quantities of metallic copper, which remains in solid solution on cooling; (5) Cuprous and ferrous sulphides are miscible in all proportions, but the mixture of highest m. pt. 1121° C., "white metal," containing 90 per cent. of cuprous sulphide, appears to be a compound, $54H_2S.FeS$.

An examination of mattes containing rising amounts of copper showed that that corresponding to white metal contained no metallic copper, but all the others contained it, the quantity increasing as the composition of the matte deviated further from that of white metal. While, however, those containing white metal and excess of ferrous sulphide contained the metallic copper in solution, those containing white metal and excess of cuprous sulphide held it mechanically, for when they were melted in a crucible out of contact with air, a portion of metallic copper gradually collected at the bottom, and was found on cooling. These mattes all contained small amounts of cuprous oxide, but none was found in the mattes with excess of ferrous sulphide. These results were confirmed by the micrographic examination of the mattes, after etching with silver nitrate or potassium cyanide. Metallic copper seems, therefore, to be formed from cuprous sulphide, but not from white metal, and is thus only produced from a white metal matte as the white metal is broken up by oxidation and separates cuprous sulphide. The effect of ordinary impurities in mattes is to displace sulphur in combination with iron, and thus, by lessening the amount of ferrous sulphide present, lessen the amount of white metal that can be formed, and hence facilitate the separation of metallic copper from a matte of given copper content. An ordinary impure matte containing antimony and arsenic, with 72 per cent. of copper, is made up of 14 per cent. of cuprous sulphide and 83 per cent. of white metal; whilst a pure matte of the same copper content consists of only 2 per cent. of cuprous sulphide and 97 per cent. of white metal. Industrial practice bears out the view that the copper is more readily separated from a matte when it contains a certain amount of impurities. —J. T. D.

Aluminium; Action of Silicon on Pure and Impure —. Aluminosilicides. E. Vigouroux. Comptes rend., 1905, 141, 951-953.

PURE silicon and aluminium, whether fused together, or whether the silicon be formed from silica by the thermite process in presence of excess of aluminium, refuse to combine, but when they are in presence of a third metal, double silicides of aluminium and the metal, or *aluminosilicides* of the metal, are formed. These are definite, crystalline substances, with metallic lustre, dense, hard, and brittle; some are attacked by dilute acids, but most of them resist all acids, even when concentrated, save hydrofluoric acid, and none of them is affected by solutions of alkali. They are formed by heating the three elements together in an atmosphere of hydrogen, or by the thermite method from mixtures of silica and metallic oxide, using excess of aluminium, or by acting with aluminium on a mixture of the metal or its oxide or sulphide with potassium silicofluoride. In view of these facts, clay vessels should be avoided in the preparation of metals which can form aluminosilicides (and practically all save lead, tin, and antimony do form them). —J. T. D.

Manganese Deposits in Cape Colony. Board of Trade J., Dec. 21, 1905.

THE discovery of rich deposits of manganese ore is reported in the Paarl district, situated at about 38 miles from Cape Town on the main railway line to the Orange River Colony and the Transvaal. The ore obtained is stated to be of a quality as good as any yet discovered in South Africa, and compares favourably with that obtained in Southern Russia and Japan. An analysis of the ore taken from the surface showed it to contain 71.5 per cent. of manganese dioxide, and it is consequently considered of a suitable quality for export. The Government analyst found 56.6 per cent. of manganese in the specimen submitted to him. [T.R.]

Mineral Deposits in Cumberland. Chem. Trade J., Dec. 16, 1905.

A new discovery of wolfram, also Scheelite (tungstate of lime) is reported in the Borrowdale district of Cumberland. The magnesian limestone deposits near Whitehaven are to be reopened at an early date. Greater activity is now being shown in blonde and lead mining in Cumberland than for some years past, and the old lead mines of the Pennine ranges in Westmoreland are being reopened. [T.R.]

ENGLISH PATENTS.

Ores or like Material: Apparatus for Use in Separating Certain Constituents of Subdivided —. (Flotation by means of a Vacuum.) F. E. Ebbott, London. Eng. Pat. 29,282, Dec. 31, 1904.

THE apparatus consists of a vessel, the horizontal cross-section of which diminishes in area from below upwards, e.g., in a vat with conical cover. This cover has an outlet at the top communicating with a chamber, preferably of glass, from which the air is exhausted, and also with a pipe dipping into a vat, through which pipe liquid and any floated material escapes from the main vat. At the bottom of the main vat there is a circumferential trough with an exit pipe dipping into a small vat; through this pipe liquid and unfloated material escape from the main vat. The material in the latter is kept in motion by a rake or stirrer on the bottom of the vat; two of the teeth of the stirrer also dip into the circumferential trough. From a third smaller vat the ore, in the state of pulp mixed with water, is fed into the main vessel through a siphon or other pipe at such a rate that some of the liquid must overflow through the opening at the top of this vessel. The latter may be heated, if necessary, by a jacket or by coils placed inside. If the electrolytic process described in Eng. Pat. 13,578 of 1904 (this J., 1905, 932) is to be used, the vat is made of conducting material and forms one electrode, whilst the stirrer, which in this case is insulated from the vat, forms the other. The length of the inlet and exit pipes must be calculated so as to work with the reduced pressure inside the vat; otherwise, valves, &c., may be used.—A. G. L.

Blast Furnaces, Converters, or the like: Means for Treating Air for Supply to —. E. Hesketh, London, and F. A. Wilcox, Sunderland, Durham. Eng. Pat. 3420, Feb. 18, 1905.

FOR the purpose of drying the hot air coming from the blowing engines, the air is passed up a vertical cylindrical vessel in which it meets a spray of cold water or other liquid, which escapes at the bottom through a trap, whilst the air is made to pass tangentially through another vessel, the drops of condensed moisture being deposited on the walls of this vessel, whilst the air leaves by a central pipe, on its way to the heater and blast-furnace, &c. The first cylinder may be fitted with baffle-plates, and two, or more, vessels may be used in conjunction so as to effect the cooling in stages.—A. G. L.

Iron: Treatment of Chromiferous —. H. H. Campbell, Steelton, U.S.A. Eng. Pat. 12,552, June 19, 1905.

SEE U.S. Pat. 795,193 of 1905; this J., 1905, 893.—T. F. B.

Aluminium or its Alloys: Process for Casting —. A. F. Cothias, Ivry-Port, France. Eng. Pat. 15,649, July 31, 1905. Under Int. Conv., Sept. 27, 1904.

THE aluminium or alloy is cast in a metal mould, preferably of cast-iron, previously heated to a temperature above the fusing point of the aluminium or alloy, and the whole is then allowed to cool slowly and gradually, whereby the metal is caused to fit the mould exactly.—A. G. L.

UNITED STATES PATENTS.

Steel: Apparatus for Making —. F. E. Young, Canton, Ohio. U.S. Pat. 801,500, Oct. 10, 1905.

THE invention relates to a converter for the manufacture of malleable iron or steel from molten iron. The converter consists of a vessel longer in one direction than in the other, and wider in the middle than at the ends. It is lined with refractory material such as fire-brick, and the top is covered over by fire-brick slabs set on edge. At one end of the converter is an opening into which the blast-pipe is inserted, and at the opposite end is an outlet opening, preferably about the same size as the inlet; both of the openings are located at or near the surface of the molten iron contained in the converter, and the cover of the converter is only a short distance above this surface. The object of the invention is, it is stated, to oxidise the molten metal slowly, more perfectly and without agitation, and to utilise the blast for removing the slag from the surface of the metal; and it is claimed that in the apparatus described, all the distinctive features of the Bessemer, the hand-puddling and open-hearth processes can be combined. The method of working, which has been claimed in a separate patent (see U.S. Pat. 724,770 of 1903; this J., 1903, 557), consists in projecting the blast, which can be made oxidising, reducing or neutral at will, under constant pressure directly across the entire surface of the molten metal, whereby all slag or scoria is removed by the blast as soon as it rises; setting the metal into a rolling motion by the mechanical action of the blast on its surface; and "holding the air in close contact with the metal in proportion to the pressure of the blast."—A. S.

Steel: Manufacture of —. H. W. Lash, Assignor to the Garrett-Cromwell Engineering Co., Cleveland, Ohio. U.S. Pat. 805,563, Nov. 28, 1905.

Iron: Method of Producing —. R. Baggaley, Pittsburg, Pa. U.S. Pat. 805,830, Nov. 28, 1905.

THE fumes from metallurgical furnaces, in which ores or mattes containing iron and sulphur are treated, are passed through a screen of combustible material, which thereby becomes encrusted with substances containing iron and sulphur. The screen is subsequently burned to sublime the sulphur, and the iron is recovered from the residue.—A. S.

Iron: Compound for Hardening —. C. A. Burns and C. E. Raab, Pittsburg, Pa. U.S. Pat. 806,080, Nov. 28, 1905.

THE compound contains sodium chloride (3 parts), alum (3), ammonium carbonate (3), potassium carbonate ("salt of tartar") (3), potassium cyanide (1), potassium nitrate (3), potassium ferriocyanide (1), and potassium ferrocyanide (1 part).—E. S.

pig iron, and 76.9 per cent. of the steel last year. The United States alone made 36.4 per cent. of the pig iron, and 38.3 per cent. of the total steel. [T.R.]

Gold; Solubility of — in Thiosulphates and Thiocyanates. H. A. White. J. Chem. Metall. and Min. Soc. of S. Africa, 1905, 8, 109-111.

SOLUTIONS of sodium thiosulphate, sodium sulphide, ammonium thiocyanate, ferric sulphate, or ferric chloride, separately, and in the cold, are practically without action on gold (a boiling solution of ferric chloride readily dissolves gold); but sodium thiosulphate and ferric chloride together dissolve it, and the action of ammonium thiocyanate and ferric chloride together is still more marked. Other oxidising agents added to the thiocyanate are also effective, but none more so than ferric salts. Experiments in which gold was suspended in these liquids for some days showed that the action gradually slackened, no doubt from the conversion of ferric into ferrous salt and the consequent lack of oxygen. The presence of ferric salts from oxidation of pyrites, and the formation of thiocyanates from cyanides, no doubt account for the flow of gold from dumps, and the enrichment of the soil below the heap, which have been frequently observed. By means of a process founded on this action of thiocyanates, it may be possible to recover considerable quantities of gold from old residue heaps. —J. T. D.

Platinum; Solubility of — in Sulphuric Acid. M. Delépine. Comptes rend., 1905, 141, 1063-1015.

THE rapidity with which concentrated sulphuric acid attacks platinum (this J., 1905, 1302) varies greatly with the conditions of experiment. When the concentrated acid is boiled with platinum foil in a flask (338° C.), it turns distinctly yellow in half an hour, and the platinum dissolves at the rate of about 0.01 gm. per sq. decim. per hour. In a basin or other open vessel the attack is much slower, because the temperature is kept down by evaporation. In mixtures of 50 grms. of sulphuric acid with 10 grms. and 20 grms. of potassium sulphate, which boil respectively at 350°-355° and 365°-370° C., the rates of attack are 0.04-0.05 and 0.12-0.13 gm. per sq. decim. per hour respectively. Traces of nitric acid, up to 0.1 per cent., added to pure sulphuric acid, do not sensibly affect the rate of attack, so that the attack of platinum by ordinary "commercially pure" sulphuric acid is not to be attributed to the traces of nitric acid which it may contain. Ammonium sulphate exercises a marked retarding influence; indeed, if to a sulphuric acid solution of platinum, ammonium sulphate be added, and the solution boiled, practically the whole of the platinum is precipitated, and no more is found in solution until the whole of the ammonium salt is destroyed. Spongy platinum is dissolved more rapidly by sulphuric acid than the compact metal, but the difference is probably one of surface only, and not due to any allotropic difference. The reaction of sulphuric acid on platinum is represented by the equation $4H_2SO_4 + Pt = Pt(SO_4)_2 + 2SO_2 + 4H_2O$; a platinum sulphate being formed. —J. T. D.

Copper Smelting; Constitution of Mattes produced in —. A. Gibb and R. C. Phelp. Trans. Amer. Inst. Min. Eng., 1905, Nov., 1193-1209.

THE mattes produced in modern copper-smelting vary in copper-content from 20 to 80 per cent., but mostly contain about 50 per cent. The amounts of arsenic, antimony, &c., contained in them are usually so small that they may be looked on as impurities simply, the essential constituents being copper, iron, and sulphur. In modern practice, where the work is done in a blast-furnace, the furnace atmosphere is oxidising, and no reduction of iron occurs. Names are given to the mattes according to their appearance:—"Coarse metal," with 35-55 per cent. of copper, hard, compact, dull bronze-colour, no visible metallic copper; "Blue metal," 60-70 per cent., bluish purple, with visible "moss copper"; "white metal," 70-76 per cent., white, unevenly plated appearance, usually homogeneous; 78-81 per cent., various names (e.g., "pinple metal," "close regule," "spongy regule," &c., according to appearance), show metallic copper in considerable proportion.

The authors find that, after determining the ultimate composition of a matte, its proximate constitution can in most cases be determined by the reaction upon it of solution of silver nitrate, from which metallic copper separates silver, cuprous sulphide, silver and silver sulphide, cuprous oxide, silver and basic copper nitrate, while ferrous sulphide is without action upon it, and iron acts so slowly that its reaction in any short time is negligible. Aided by this mode of analysis, they find that:—(1) Cuprous sulphide is the only compound of copper and sulphur stable in the melted condition; it will dissolve neither copper nor sulphur; (2) Ferrous sulphide is the only stable compound of iron and sulphur; it will take up no more sulphur, but much more iron, which, however, forms on cooling a solid solution, and not a compound; (3) Iron will decompose cuprous sulphide, and the action is reversible, equilibrium occurring when the mixture contains about 30 per cent. of ferrous sulphide; (4) Ferrous sulphide dissolves large quantities of metallic copper, which remains in solid solution on cooling; (5) Cuprous and ferrous sulphides are miscible in all proportions, but the mixture of highest m. pt. 1121° C., "white metal," containing 90 per cent. of cuprous sulphide, appears to be a compound, $54H_2S.FeS$.

An examination of mattes containing rising amounts of copper showed that that corresponding to white metal contained no metallic copper, but all the others contained it, the quantity increasing as the composition of the matte deviated further from that of white metal. While, however, those containing white metal and excess of ferrous sulphide contained the metallic copper in solution, those containing white metal and excess of cuprous sulphide held it mechanically, for when they were melted in a crucible out of contact with air, a portion of metallic copper gradually collected at the bottom, and was found on cooling. These mattes all contained small amounts of cuprous oxide, but none was found in the mattes with excess of ferrous sulphide. These results were confirmed by the micrographic examination of the mattes, after etching with silver nitrate or potassium cyanide. Metallic copper seems, therefore, to be formed from cuprous sulphide, but not from white metal, and is thus only produced from a white metal matte as the white metal is broken up by oxidation and separates cuprous sulphide. The effect of ordinary impurities in mattes is to displace sulphur in combination with iron, and thus, by lessening the amount of ferrous sulphide present, lessen the amount of white metal that can be formed, and hence facilitate the separation of metallic copper from a matte of given copper content. An ordinary impure matte containing antimony and arsenic, with 72 per cent. of copper, is made up of 14 per cent. of cuprous sulphide and 83 per cent. of white metal; whilst a pure matte of the same copper content consists of only 2 per cent. of cuprous sulphide and 97 per cent. of white metal. Industrial practice bears out the view that the copper is more readily separated from a matte when it contains a certain amount of impurities. —J. T. D.

Aluminium; Action of Silicon on Pure and Impure —. Aluminosilicides. E. Vigouroux. Comptes rend., 1905, 141, 951-953.

PURE silicon and aluminium, whether fused together, or whether the silicon be formed from silica by the thermite process in presence of excess of aluminium, refuse to combine, but when they are in presence of a third metal, double silicides of aluminium and the metal, or *aluminosilicides* of the metal, are formed. These are definite, crystalline substances, with metallic lustre, dense, hard, and brittle; some are attacked by dilute acids, but most of them resist all acids, even when concentrated, save hydrofluoric acid, and none of them is affected by solutions of alkali. They are formed by heating the three elements together in an atmosphere of hydrogen, or by the thermite method from mixtures of silica and metallic oxide, using excess of aluminium, or by acting with aluminium on a mixture of the metal or its oxide or sulphide with potassium silicofluoride. In view of these facts, clay vessels should be avoided in the preparation of metals which can form aluminosilicides (and practically all save lead, tin, and antimony do form them). —J. T. D.

vided on its exterior with longitudinal ribs parallel to the shaft. The annular space within the drum is divided into compartments by radial partitions, and the outer wall of the drum has openings or tuyères between the longitudinal ribs. Into each open end of the drum projects a conical casing, through which passes a pipe ending in a perforated ring opposite the end of the drum. The molten slag is delivered through a shoot directly from the blast-furnace on to the outer surface of the drum, which is made to rotate at great speed. Aqueous solutions are forced, under pressure, through the pipes and perforated rings into the compartments within the drum, whence, mixed with air, drawn in through the conical casings, they issue through the openings in the outer wall of the drum, and effect the granulation of the slag. It is stated that the small proportion of water in the aqueous solutions is immediately vaporised, and that the granulated slag does not need subsequent drying.—A. S.

Furnace: Rotary — for the Production of Gas, or for Roasting (Ores, &c.). S. E. Sicurin. Fr. Pat. 356,615, Aug. 3, 1905. II., page 11.

Ores: Process and Apparatus for the Mechanical Preparation of Powdered —. F. Windhausen. Fr. Pat. 357,120, Aug. 22, 1905.

The finely powdered ore is carried by a current of air or gas into a hollow cylinder or drum rotating rapidly on a horizontal, inclined or vertical axis, or into a fixed drum in which a shaft carrying blades or wings is rapidly rotated. The heavy particles of ore are thrown against the inner wall of the drum, whilst the lighter particles are carried away, entrained by the air. The air charged with the ore may be passed through two or more rotating drums in succession rotating at different speeds, or the centrifugal force may be varied in other ways. Claim is also made for the introduction of a liquid such as water into the drum or drums, to assist in retaining the heavy particles on the wall of the latter, or it may be introduced in sufficient quantity to continuously remove the heavy particles.—A. S.

XL—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Nitrogen: Utilisation of Atmospheric —. O. N. Witt. Chem. Ind., 1905, 28, 690-707.

THE author reviews the processes which have been devised for the utilisation of atmospheric nitrogen. Frank's method (this J., 1903, 809) appears to have met with a certain amount of success, but it depends upon the cheap production of electrical power and also of pure nitrogen. At the present time the most promising process appears to be that of Birkeland and Eyde (Fr. Pat. 335,692 of 1903; U.S. Pat. 772,862 of 1904, and Eng. Pat. 3525 of 1905; this J., 1904, 193, 1097; 1905, 895; also this J., 1904, 1096), which is in operation at Notodden, Norway. The nitrogen compounds are absorbed in towers, and the weak acid is used over and over again in the towers until it attains a strength of 50 per cent. The gases, leaving the absorbing towers, are next passed through milk of lime and then over dry lime, calcium nitrite being chiefly produced. This is treated with nitric acid, and the nitrous acid evolved is oxidised, the nitric acid formed being absorbed in the absorbing-towers. At present, the whole of the nitric acid is fixed as calcium nitrate. (For the utilisation of calcium nitrate as a fertiliser, see this J., 1905, 628, 1245.) In accordance with a suggestion by R. Messel, the normal calcium nitrate is converted by addition of quicklime or calcium sulphate, into basic nitrate, which forms a practically non-hygroscopic powder of great value as a fertiliser. The final product may, however, be obtained as nitric acid, or other nitrates, or nitrites. The daily production now amounts to 1500 kilos. of anhydrous nitric acid, and an output of 500-600 kilos. of nitric acid per kilowatt-year can be regularly maintained. The production will be greatly increased as more water-power is brought under control. The total amount of water-power available for the production of electrical energy is estimated at over

350,000 h.p., and it is stated that it will be possible to generate electrical power at the low price of M.12 per horse-power year.—A. S.

Ammonia: Electrolytic Oxidation of — and its Dependence on the Nature of the Anode. E. Müller and F. Spitzer. Z. Elektrochem., 1905, 11, 917-931.

AQUEOUS solutions of ammonia containing sodium hydroxide were submitted to electrolysis in cells in which the anode and cathode chambers were separated by a diaphragm. In some cases metallic salts were added to the anode solution. The main results may be summarised as follows:—The course of the oxidation varies considerably according to the nature of the metal used for anode. Upon platinum anodes the potential is high, and the chief products are gaseous nitrogen and some nitrate, only traces of oxygen and nitrite being detected. In this case, however, some 23 per cent. of the current is also used up in effecting some other oxidation, the nature of which has not been discovered. With anodes of copper, nickel, iron and cobalt, the potential is lower and the products are gaseous oxygen and nitrogen and nitrite; in the case of cobalt, nitrate is also formed.

When a platinum anode is employed, and salts of copper, nickel, cobalt or silver are added to the solution, the resulting products are similar to those obtained with anodes of these metals.

In most cases, with the addition of metallic salts to the solution, the oxide of the metal is deposited upon the anode, and it is probable that the results are to be attributed not only to the difference in anode potential, but also to the catalytic effect of such oxide films.—R. S. H.

Chlorine: Analysis of Electrolytic —. F. P. Treadwell and W. A. K. Christie. XXIII., page 42.

ENGLISH PATENTS.

Thermo-Electric Generators: Couples for Sulphide of Copper —. Comp. Thermo-Electrique (System Hermite) Soc. Anon., Paris. Eng. Pat. 11,301, May 30, 1905. Under Int. Conv., May 3, 1905.

THIS invention relates to a method of manufacturing bodies of sulphide of copper for thermo-electric couples in an annular or other form, the sulphide being first pulverised, and then compressed in moulds for the purpose of insuring a uniform electrical resistance in the bodies. The sulphide is compressed in a mould, after placing within the latter the inner and outer metal casings, which are to carry the sulphide. After compression, the annular metal casings project beyond the body of the sulphide, and the projecting parts are cut and unrolled so as to form the conductors. Finally, the metal casings are riveted over mica and steel rings in order to form a tight joint. Metal rods or threads may be embedded in the compressed sulphide during the moulding, and the sulphide may be moulded in sectors, these being separated by plates of mica.—B. N.

Ozonisers and like Apparatus for Treating Gases Electrically. R. F. Wood-Smith, London. Eng. Pat. 6872, March 31, 1905.

THIS invention relates to ozonisers in which the electrodes have points or projections on their surfaces. The dielectrics are provided on both sides with cup-shaped or like depressions, these being arranged opposite to the projections on the electrodes.—B. N.

Electrolytic Apparatus: Impts. relating to —. C. N. Råber, Christiania, Norway. Eng. Pat. 20,898, Oct. 16, 1905. Under Int. Conv., Oct. 15, 1904.

THE apparatus is provided with a diaphragm, and filtering sheets are arranged on both sides of it, the liquid to be electrolysed entering continuously between the filtering sheets and the diaphragm.—B. N.

Electrodes: Impts. in — [for Electrolytic Manufacture of Alkali]. M. Yāsuda, Tokyo, Japan. Eng. Pat. 22,460, Nov. 3, 1905. Under Int. Conv., Jan. 21, 1905.

THE principal object of this invention is to provide a cathode, and casing for the same, for use in the electrolytic

pig iron, and 76.9 per cent. of the steel last year. The United States alone made 36.4 per cent. of the pig iron, and 38.3 per cent. of the total steel. [T.R.]

Gold; Solubility of — in Thiosulphates and Thiocyanates. H. A. White. J. Chem. Metall. and Min. Soc. of S. Africa, 1905, 8, 109-111.

SOLUTIONS of sodium thiosulphate, sodium sulphide, ammonium thiocyanate, ferric sulphate, or ferric chloride, separately, and in the cold, are practically without action on gold (a boiling solution of ferric chloride readily dissolves gold); but sodium thiosulphate and ferric chloride together dissolve it, and the action of ammonium thiocyanate and ferric chloride together is still more marked. Other oxidising agents added to the thiocyanate are also effective, but none more so than ferric salts. Experiments in which gold was suspended in these liquids for some days showed that the action gradually slackened, no doubt from the conversion of ferric into ferrous salt and the consequent lack of oxygen. The presence of ferric salts from oxidation of pyrites, and the formation of thiocyanates from cyanides, no doubt account for the flow of gold from dumps, and the enrichment of the soil below the heap, which have been frequently observed. By means of a process founded on this action of thiocyanates, it may be possible to recover considerable quantities of gold from old residue heaps. —J. T. D.

Platinum; Solubility of — in Sulphuric Acid. M. Delépine. Comptes rend., 1905, 141, 1063-1015.

THE rapidity with which concentrated sulphuric acid attacks platinum (this J., 1905, 1302) varies greatly with the conditions of experiment. When the concentrated acid is boiled with platinum foil in a flask (338° C.), it turns distinctly yellow in half an hour, and the platinum dissolves at the rate of about 0.01 gram. per sq. decim. per hour. In a basin or other open vessel the attack is much slower, because the temperature is kept down by evaporation. In mixtures of 50 grams of sulphuric acid with 10 grms. and 20 grms. of potassium sulphate, which boil respectively at 350°-355° and 365°-370° C., the rates of attack are 0.04-0.05 and 0.12-0.13 gram. per sq. decim. per hour respectively. Traces of nitric acid, up to 0.1 per cent., added to pure sulphuric acid, do not sensibly affect the rate of attack, so that the attack of platinum by ordinary "commercially pure" sulphuric acid is not to be attributed to the traces of nitric acid which it may contain. Ammonium sulphate exercises a marked retarding influence; indeed, if to a sulphuric acid solution of platinum, ammonium sulphate be added, and the solution boiled, practically the whole of the platinum is precipitated, and no more is found in solution until the whole of the ammonium salt is destroyed. Spongy platinum is dissolved more rapidly by sulphuric acid than the compact metal, but the difference is probably one of surface only, and not due to any allotropic difference. The reaction of sulphuric acid on platinum is represented by the equation $4H_2SO_4 + Pt = Pt(SO_4)_2 + 2SO_2 + 4H_2O$; a platinum sulphate being formed. —J. T. D.

Copper Smelting; Constitution of Mattes produced in —. A. Gibb and R. C. Phelp. Trans. Amer. Inst. Min. Eng., 1905, Nov., 1193-1209.

THE mattes produced in modern copper-smelting vary in copper-content from 20 to 80 per cent., but mostly contain about 50 per cent. The amounts of arsenic, antimony, &c., contained in them are usually so small that they may be looked on as impurities simply, the essential constituents being copper, iron, and sulphur. In modern practice, where the work is done in a blast-furnace, the furnace atmosphere is oxidising, and no reduction of iron occurs. Names are given to the mattes according to their appearance:—"Coarse metal," with 35-55 per cent. of copper, hard, compact, dull bronze-colour, no visible metallic copper; "Blue metal," 60-70 per cent., bluish purple, with visible "moss copper"; "white metal," 70-76 per cent., white, unevenly plated appearance, usually homogeneous; 78-81 per cent., various names (e.g., "pinple metal," "close regule," "spongy regule," &c., according to appearance), show metallic copper in considerable proportion.

The authors find that, after determining the ultimate composition of a matte, its proximate constitution can in most cases be determined by the reaction upon it of solution of silver nitrate, from which metallic copper separates silver, cuprous sulphide, silver and silver sulphide, cuprous oxide, silver and basic copper nitrate, while ferrous sulphide is without action upon it, and iron acts so slowly that its reaction in any short time is negligible. Aided by this mode of analysis, they find that:—(1) Cuprous sulphide is the only compound of copper and sulphur stable in the melted condition; it will dissolve neither copper nor sulphur; (2) Ferrous sulphide is the only stable compound of iron and sulphur; it will take up no more sulphur, but much more iron, which, however, forms on cooling a solid solution, and not a compound; (3) Iron will decompose cuprous sulphide, and the action is reversible, equilibrium occurring when the mixture contains about 30 per cent. of ferrous sulphide; (4) Ferrous sulphide dissolves large quantities of metallic copper, which remains in solid solution on cooling; (5) Cuprous and ferrous sulphides are miscible in all proportions, but the mixture of highest m. pt. 1121° C., "white metal," containing 90 per cent. of cuprous sulphide, appears to be a compound, $54H_2S.FeS$.

An examination of mattes containing rising amounts of copper showed that that corresponding to white metal contained no metallic copper, but all the others contained it, the quantity increasing as the composition of the matte deviated further from that of white metal. While, however, those containing white metal and excess of ferrous sulphide contained the metallic copper in solution, those containing white metal and excess of cuprous sulphide held it mechanically, for when they were melted in a crucible out of contact with air, a portion of metallic copper gradually collected at the bottom, and was found on cooling. These mattes all contained small amounts of cuprous oxide, but none was found in the mattes with excess of ferrous sulphide. These results were confirmed by the micrographic examination of the mattes, after etching with silver nitrate or potassium cyanide. Metallic copper seems, therefore, to be formed from cuprous sulphide, but not from white metal, and is thus only produced from a white metal matte as the white metal is broken up by oxidation and separates cuprous sulphide. The effect of ordinary impurities in mattes is to displace sulphur in combination with iron, and thus, by lessening the amount of ferrous sulphide present, lessen the amount of white metal that can be formed, and hence facilitate the separation of metallic copper from a matte of given copper content. An ordinary impure matte containing antimony and arsenic, with 72 per cent. of copper, is made up of 14 per cent. of cuprous sulphide and 83 per cent. of white metal; whilst a pure matte of the same copper content consists of only 2 per cent. of cuprous sulphide and 97 per cent. of white metal. Industrial practice bears out the view that the copper is more readily separated from a matte when it contains a certain amount of impurities. —J. T. D.

Aluminium; Action of Silicon on Pure and Impure —. Aluminosilicides. E. Vigouroux. Comptes rend., 1905, 141, 951-953.

PURE silicon and aluminium, whether fused together, or whether the silicon be formed from silica by the thermite process in presence of excess of aluminium, refuse to combine, but when they are in presence of a third metal, double silicides of aluminium and the metal, or *aluminosilicides* of the metal, are formed. These are definite, crystalline substances, with metallic lustre, dense, hard, and brittle; some are attacked by dilute acids, but most of them resist all acids, even when concentrated, save hydrofluoric acid, and none of them is affected by solutions of alkali. They are formed by heating the three elements together in an atmosphere of hydrogen, or by the thermite method from mixtures of silica and metallic oxide, using excess of aluminium, or by acting with aluminium on a mixture of the metal or its oxide or sulphide with potassium silicofluoride. In view of these facts, clay vessels should be avoided in the preparation of metals which can form aluminosilicides (and practically all save lead, tin, and antimony do form them). —J. T. D.

Insulating and other Purposes; Manufacture of Materials Suitable for — W. R. Whitney, Boston, Assignor to General Electric Co., New York. U.S. Pat. 806,608, Dec. 5, 1905.

See Eng. Pat. 12,312 of 1903; this J., 1904, 717.—T. F. B.

Insulating; Method of — W. S. Moody, Schenectady, N.Y., Assignor to General Electric Co., New York. U.S. Pat. 806,606, Dec. 5, 1905.

THE conductors of an electrical apparatus having an enclosing casing are insulated by heating oil while passing dry air through it, and then introducing the oil into the casing while maintaining a vacuum within the apparatus.

Gold; Distillation of —, and of its Alloys with Copper and with Tin. New Method of Producing Purple of Cassius. H. Moissan. Comptes rend., 1905, 141, 977—983.

GOLD can be easily distilled in the electric furnace, with a similar disposition of apparatus to that used by the author in distilling copper (this J., 1905, 1312). It boils at a higher temperature than copper and at a lower temperature than lime. It condenses on the cold tube in filiform masses and microscopic crystals, which have all the characters of ordinary gold in fine division. In alloys of gold and copper, or gold and tin, the copper or tin distils before the gold. In distilling gold-tin alloys, a finely divided mixture of stannic oxide, lime, and gold is obtained, having the colour and properties of purple of Cassius. Similar deposits of varying tint can be obtained by substituting for lime other oxides (silica, zirconia, magnesia, alumina).—J. T. D.

UNITED STATES PATENTS.

[Electrolytic] Separation of Metals [Nickel and Copper]. N. V. Hybinette, Westfield, N.J. U.S. Pat. 805,969, Nov. 28, 1905.

THE process is for the separation of nickel from copper, and consists in making an alloy of the two metals the anode in an electrolyte consisting of a solution of nickel sulphate and a "weak acid," contained in a cell divided into anode and cathode compartments by a porous diaphragm. The process is so conducted that the solution in the cathode compartment contains only nickel, whilst that in the anode compartment contains both nickel and copper, and the passage of copper through the diaphragm is prevented by causing the electrolyte to circulate from the cathode to the anode, and by maintaining a pressure in the cathode compartment. The anode solution is regenerated, i.e., freed from copper, by "concentration" on nickel or a nickel-copper alloy refined at least to the point at which carbon, silicon and sulphur are practically eliminated, and is then returned to the cathode compartment.—A. S.

Calcium; Process of Manufacturing — O. Ruff, Berlin, and W. Plato, Colberg, Germany. U.S. Pat. 806,006, Nov. 28, 1905.

A FUSED mixture of calcium chloride with calcium fluoride or some other calcium salt which will lower the melting-point is electrolysed. The temperature is maintained above the melting-point of metallic calcium.—R. S. H.

FRENCH PATENTS.

Iron; Manufacture of Molten Decarburised — Soc. Electro-Metallurgique Française. Fr. Pat. 356,714, Aug. 5, 1905.

MOLTEN steel (soft) is caused to cool, either by radiation or by addition of a certain proportion of cold iron, until it is partially or wholly solidified. During this process, the carbon in those portions of the metal that remain liquid longest (the mother-liquor) is oxidised at the expense of the iron oxide, thus leading to escape of carbon in combination with oxygen as a gas. The metal is then remelted without addition, and may be cast in ingots without becoming porous by disengagement of gases. Iron thus decarburised, may be decarburised by fusion with such a metal as aluminium, and is then suitable for making forgings, plates or castings for mechanical or electrical purposes. It is preferred to carry out the process in an electric furnace, in which any carburizing influence may be guarded against, and reference is made to the furnaces described in Fr. Pats. 298,656 and 305,317 of 1900, as suitable.—E. S.

Metals; Process and Arrangement for Extracting — from Ores and other Metalliferous Materials, by Solution and Electrolysis. Soc. Ganz et Cie. Fr. Pat. 356,825, Aug. 11, 1905. Under Int. Conv., Aug. 26, 1904.

THE apparatus consists of a vessel divided into two portions by a false bottom E, thus forming an electrolytic chamber F, and a lixiviating chamber H. The electrolyte, consisting of an alkali salt or a mixture of this with a metallic salt, is supplied through the tube K in connection with c, the latter also serving to connect the source of current with the anodes b. The latter, preferably of graphite, form a kind of grid through which the electrolyte passes, and immediately above the anodes is a series of diaphragm tubes d. The latter are connected together in sets of eight to a common pipe f, so that the cathode liquid in the tubular diaphragms may traverse them uniformly. The tubular diaphragms d are inclined or horizontal, and constructed of alkali-resisting material, containing the cathodes h advantageously constructed of iron or nickel. A suitable piece of metal connects the cathode with the source of current j, which is made tight in a branch tube i fixed in the head-piece g. The latter is connected by a union at k with the collecting vessel l for the alkali; an alkali salt is passed, by means of f, through the tubular diaphragms, and the mixture of alkali salt, alkali hydroxide,

pig iron, and 76.9 per cent. of the steel last year. The United States alone made 36.4 per cent. of the pig iron, and 38.3 per cent. of the total steel. [T.R.]

Gold; Solubility of — in Thiosulphates and Thiocyanates. H. A. White. J. Chem. Metall. and Min. Soc. of S. Africa, 1905, 8, 109-111.

SOLUTIONS of sodium thiosulphate, sodium sulphide, ammonium thiocyanate, ferric sulphate, or ferric chloride, separately, and in the cold, are practically without action on gold (a boiling solution of ferric chloride readily dissolves gold); but sodium thiosulphate and ferric chloride together dissolve it, and the action of ammonium thiocyanate and ferric chloride together is still more marked. Other oxidising agents added to the thiocyanate are also effective, but none more so than ferric salts. Experiments in which gold was suspended in these liquids for some days showed that the action gradually slackened, no doubt from the conversion of ferric into ferrous salt and the consequent lack of oxygen. The presence of ferric salts from oxidation of pyrites, and the formation of thiocyanates from cyanides, no doubt account for the flow of gold from dumps, and the enrichment of the soil below the heap, which have been frequently observed. By means of a process founded on this action of thiocyanates, it may be possible to recover considerable quantities of gold from old residue heaps. —J. T. D.

Platinum; Solubility of — in Sulphuric Acid. M. Delépine. Comptes rend., 1905, 141, 1063-1015.

THE rapidity with which concentrated sulphuric acid attacks platinum (this J., 1905, 1302) varies greatly with the conditions of experiment. When the concentrated acid is boiled with platinum foil in a flask (338° C.), it turns distinctly yellow in half an hour, and the platinum dissolves at the rate of about 0.01 gram. per sq. decim. per hour. In a basin or other open vessel the attack is much slower, because the temperature is kept down by evaporation. In mixtures of 50 grams of sulphuric acid with 10 grams and 20 grams of potassium sulphate, which boil respectively at 350°-355° and 365°-370° C., the rates of attack are 0.04-0.05 and 0.12-0.13 gram. per sq. decim. per hour respectively. The authors find that, after determining the ultimate composition of a matte, its proximate constitution can in most cases be determined by the reaction upon it of solution of silver nitrate, from which metallic copper separates silver, cuprous sulphide, silver and silver sulphide, cuprous oxide, silver and basic copper nitrate, while ferrous sulphide is without action upon it, and iron acts so slowly that its reaction in any short time is negligible. Aided by this mode of analysis, they find that:—(1) Cuprous sulphide is the only compound of copper and sulphur stable in the melted condition; it will dissolve neither copper nor sulphur; (2) Ferrous sulphide is the only stable compound of iron and sulphur; it will take up no more sulphur, but much more iron, which, however, forms on cooling a solid solution, and not a compound; (3) Iron will decompose cuprous sulphide, and the action is reversible, equilibrium occurring when the mixture contains about 30 per cent. of ferrous sulphide; (4) Ferrous sulphide dissolves large quantities of metallic copper, which remains in solid solution on cooling; (5) Cuprous and ferrous sulphides are miscible in all proportions, but the mixture of highest m. pt. 1121° C., "white metal," containing 90 per cent. of cuprous sulphide, appears to be a compound, $54H_2S.FeS$.

An examination of mattes containing rising amounts of copper showed that that corresponding to white metal contained no metallic copper, but all the others contained it, the quantity increasing as the composition of the matte deviated further from that of white metal. While, however, those containing white metal and excess of ferrous sulphide contained the metallic copper in solution, those containing white metal and excess of cuprous sulphide held it mechanically, for when they were melted in a crucible out of contact with air, a portion of metallic copper gradually collected at the bottom, and was found on cooling. These mattes all contained small amounts of cuprous oxide, but none was found in the mattes with excess of ferrous sulphide. These results were confirmed by the micrographic examination of the mattes, after etching with silver nitrate or potassium cyanide. Metallic copper seems, therefore, to be formed from cuprous sulphide, but not from white metal, and is thus only produced from a white metal matte as the white metal is broken up by oxidation and separates cuprous sulphide. The effect of ordinary impurities in mattes is to displace sulphur in combination with iron, and thus, by lessening the amount of ferrous sulphide present, lessen the amount of white metal that can be formed, and hence facilitate the separation of metallic copper from a matte of given copper content. An ordinary impure matte containing antimony and arsenic, with 72 per cent. of copper, is made up of 14 per cent. of cuprous sulphide and 83 per cent. of white metal; whilst a pure matte of the same copper content consists of only 2 per cent. of cuprous sulphide and 97 per cent. of white metal. Industrial practice bears out the view that the copper is more readily separated from a matte when it contains a certain amount of impurities. —J. T. D.

Aluminium; Action of Silicon on Pure and Impure —. Aluminosilicides. E. Vigouroux. Comptes rend., 1905, 141, 951-953.

PURE silicon and aluminium, whether fused together, or whether the silicon be formed from silica by the thermite process in presence of excess of aluminium, refuse to combine, but when they are in presence of a third metal, double silicides of aluminium and the metal, or aluminosilicides of the metal, are formed. These are definite, crystalline substances, with metallic lustre, dense, hard, and brittle; some are attacked by dilute acids, but most of them resist all acids, even when concentrated, save hydrofluoric acid, and none of them is affected by solutions of alkali. They are formed by heating the three elements together in an atmosphere of hydrogen, or by the thermite method from mixtures of silica and metallic oxide, using excess of aluminium, or by acting with aluminium on a mixture of the metal or its oxide or sulphide with potassium silicofluoride. In view of these facts, clay vessels should be avoided in the preparation of metals which can form aluminosilicides (and practically all save lead, tin, and antimony do form them). —J. T. D.

Fig. 2

id soap is supplied from below through the conduit (Fig. 2), which is in connection with the mould chambers by connecting apertures, closed by longitudinally displaceable rods *d* (Fig. 1). The latter have chamfered upper ends *e* (Fig. 1), entering these connecting apertures, and completely filling them when they are retracted, thus preventing the soap from collecting and solidifying in them. The plates of soap, which set in the local separate cooling chambers *a*, are ejected in horizontal direction by means of a displaceable apparatus the "knock-outs" *m* entering the mould chambers and delivering the soap on to a movable stand *C*. The plates of soap may be divided simultaneously with their ejection by means of cutting wires, knives, or the like, mounted on *A* or *C*. The "knock-outs" *m* (Fig. 2) are arranged step-wise, so that the plates of soap are attacked successively and not simultaneously. The ejecting apparatus *B* is moved against the cooling apparatus *A* by means of racks *n*, the latter being fixed to *A* and guided by *g*, and engaging with winding gear, *p*, *q*, *r*, *s*, *t*, mounted on *B*.—B. N.

Washing Powder Containing Alkali Superoxide; Method of Packing and Storing —, and Device therefor. V. P. Thompson, Liverpool. From Königswater and Schell, Linden, Germany. Eng. Pat. 19,809, Sept. 30, 1905.

A cylindrical vessel is filled with soap powder, or a mixture of soap powder and stearic or other suitable fatty acid. A second tube, arranged concentrically with this, attached to its lid and reaching almost to the bottom which is fitted upon both, contains sodium peroxide, or other "alkali superoxide." The coupling of the two tubes is done after the lid has been secured to the outer tube and before the bottom is put on. Discharging appliance may be placed in the inner tube, being attached to the bottom by means of a wire, for the purpose of retaining the sodium peroxide and aiding in its contact with the soap powder when the lid is withdrawn. The object is to keep these compounds, which form the chief ingredients of a washing powder, apart from each other, until the powder is about to be used, the composition of the sodium peroxide, which occurs when it is mixed with moist soap powder, being thus aided, and the two substances being mixed at the moment when the package containing them is opened. See also this J., 1905, 1011.)—E. B.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc

(A.)—PIGMENTS, PAINTS.

White and Red Lead.

The following is an abstract of a memorandum issued by the White Lead Corroders' Trade Section of the London Chamber of Commerce:—

It has come to the knowledge of the Section that users of white and red lead, especially small buyers, have been misled in buying as "Best," "Genuine," or other term implying the highest quality, a pigment which on analysis has been found to be adulterated, and the Section desire to draw attention to the fact that it is a distinct breach of the Merchandise Marks Act, 1887, to describe and sell "Best," "Genuine," or other similar term any white or red lead which contains any adulterant such as barytes, or any other foreign added matter. The penalties attaching to the use of misleading terms under the Mer-

chandise Marks Act are heavy, so that it behoves everyone in the trade to take due precautions against their offering, or having in their possession for sale, white or red lead which bears a misleading description within the meaning of the Act. In this connection the White Lead Section of the Chamber are prepared to examine and report on, free of charge, any sample of white or red lead bought as "Best," "Genuine," or other term indicating the highest quality, if a small sample of the same is sent to "The Inspector," White Lead Corroders' Trade Section, London Chamber of Commerce, Oxford Court, London, E.C. A half-pound sample will be sufficient for the purpose of analysis. [T.R.]

ENGLISH PATENT.

[Antimony Oxide] "White Antimony" Pigment; Manufacture of —. L. Brancot, Brioude, France. Eng. Pat. 16,490A, Aug. 14, 1905. Under Int. Conv., April 15, 1905.

ANTIMONY oxide is mixed with a solution of barium salts or hydroxide, or with a milk of barium or calcium carbonate, these latter compounds being converted into the corresponding sulphites by treating them with the sulphurous gases from the roasting of antimony ore.—C. S.

UNITED STATES PATENTS.

Caseinine [Disperser] Compositions; Process for Preparing —. H. H. Church, Bellows Falls, Vt., Assignor to Casein Co. of America, New Jersey. U.S. Pat. 805,712, Nov. 28, 1905.

SOAP is added to a warm aqueous solution of glue and the mixture dried in the form of films. The latter are then powdered and mixed with a suitable proportion of a pulverised mineral or earthy base, such as talc or whiting, or both.—W. P. S.

Paint; Process of Treating —. M. E. McMaster, Monroe City, Mo. U.S. Pat. 805,984, Nov. 28, 1905.

THE process consists in adding a solution of mercuric chloride to sweet milk, thoroughly incorporating and heating the mixture, and stirring it into the paint. —W. C. H.

FRENCH PATENTS.

Colour [Compound] Resistant to Light and to Weather Changes. W. Hoffmeister, H. Hündt, C. Eiter, and A. Winther. Fr. Pat. 356,663, July 27, 1905.

THE colouring matter is composed of an agglutinant, such as potassium silicate, or, in some cases, casein or the like, mixed with finely-powdered coloured materials, such as glass, porcelain or sand, or a suitable coloured mineral. Surfaces treated with a paste thus prepared may be washed with acids, chloride of lime, or alcohol, to prevent an efflorescence.—E. S.

Paint with Resin Base. F. Büttner Pfäffer zu Thal. Fr. Pat. 356,988, Aug. 19, 1905.

THE pigment is incorporated with finely-divided, soft oleum resin, the resulting mass, which keeps in good condition for a long time, being thinned down with some more or less volatile solvent for use.—C. S.

(B.)—RESINS, VARNISHES.

UNITED STATES PATENT.

Wood; Apparatus for Fiberizing and Deriving other Products from —. A. W. Handford, Evanston, Assignor to Wood Distillates and Fibre Co., Chicago. U.S. Pat. 806,253, Dec. 5, 1905.

THE apparatus consists of a device for comminuting the wood, a digester for the comminuted wood, pairs of rollers enclosed in a suitable casing, for expressing the liquid from the pulp, and a pump connected with the last two receptacles, for leading the liquids containing the resinous products of the wood to an apparatus for working them up. Endless conveyors are provided for conveying the product at each stage of the process to the succeeding operation.—T. F. B.

(C.)—INDIA-RUBBER, Etc.

Caoutchouc; Existence of Vessels Bearing —, in a Genus of Menispermaceæ. J. Maheu. *Comptes rend.*, 1905, 141, 958—959.

Most of the known species of *Tinomisium* (Miers) contain lactiferous vessels in their parenchyma, which contain a considerable proportion of caoutchouc. No menispermaceous plant has hitherto shown the presence of caoutchouc.—J. T. D.

Caoutchouc from the Bark of "Mascarenhasia longifolia." H. Jumelle. "Lo Caoutchouc et la Gutta Percha," 2 [8]; through *Gummi-Zeit.*, 1905, 20, 232—233.

THE author has made experiments on the extraction of rubber from the bark of the Madagascarese rubber plant *Mascarenhasia longifolia* by the following three processes:—

1. *Deiss Process of Treatment with Sulphuric Acid* (see Eng. Pat. 12,538 of 1899; this J., 1899, 927).—After freeing the rubber from acid and bark by washing between rolls with hot water, or grinding wet in a porcelain mortar, washing and sifting, a yield of 4.6 per cent. on the weight of bark used was obtained.

2. *Hamet's Method.*—The crushed bark was heated for two hours at 130° C. in an autoclave with a 15 per cent. solution of sodium carbonate, and the product was washed on a sieve. The yield was again 4.6 per cent. on the weight of bark used. The rubber obtained by this and the preceding process rapidly darkens in colour.

3. *Process of Arnaud, Verneuil and Godefroy-Lebœuf* (see this J., 1900, 256; also Eng. Pat. 9906 of 1900; this J., 1901, 373).—The yield obtained by this process was only 3 per cent. on the weight of bark used, but the rubber was not so dark coloured as that obtained by the other processes.

From *Haucornia speciosa* Arnaud obtains by his process 5 per cent., from *Landolphia Heudelotii* 5.8 per cent. of commercial rubber.

The following table contains the results of comparative analyses of rubber: (1) from the latex and (2) from the bark of *Mascarenhasia longifolia*, the former being prepared by sulphuric acid coagulation:—

	Rubber from latex.	Rubber from bark.		
		Deiss.	Hamet.	Arnaud.
Moisture ..	5.66	6.20	3.30	11.02
Rubber soluble in ether ..	65.93	62.70	61.79	62.00
Resins soluble in other alcohol ..	4.27	—	—	—
Foreign substances ..	28.41	—	—	—
Ash* ..	0.75	1.87	2.92	2.83
Rubber soluble in ether, calculated on dry substance ..	69.88	66.84	69.66	63.89

* Ash to bark=1.31 per cent.

Caoutchouc; Study of Different Kinds of —. The Relation between the Hydrocarbons of Caoutchouc and Gutta-Percha. C. Harries. *Ber.*, 1905, 38, 3985—3989.

THE author has extended his method of determining the chemical nature of Para-caoutchouc (ozone-method, *Ber.*, 1904, 37, 2708; this J., 1904, 830; *Ber.*, 1905, 38, 1195; this J., 1905, 448) to the hydrocarbons from gutta-percha, which Ramsay (this J., 1902, 1367) and Tschireh (Annalen, 1905, 243, 114) agree in describing as a white, crystalline mass of the composition $C_{10}H_{16}$, which is oxidised more readily by the oxygen of the air than caoutchouc. It has already been shown that pure gutta-percha gives a nitrosite $C_{10}H_{15}N_3O_2$, similar to that derived from caoutchouc (*Ber.*, 1903, 36, 1938; this J., 1903, 875), and it is now found to give a quantitative yield of diazonido, $C_{10}H_{15}O_8$, on treatment with ozone. The ozonide has the same molecular weight and yields on hydrolysis the same products, viz. levulinic aldehyde or acid and levulinic aldehyde-diperoxide,

as the caoutchouc ozonide. The proportions of aldehyde to acid in the products of hydrolysis are, however, reversed in the two cases, being 1.3 to 2.9 in the case of the gutta ozonide, and 2.3 to 1.0—1.5 in the case of the caoutchouc derivative. The author considers that the ozonide molecule probably splits up in a different way in each case, and he illustrates these by graphic formulae of some complexity.

The reason for the difference in the way in which the two molecules break down is probably to be sought for in a *cis-trans* isomerism of the two ozonides, having its origin in a stereochemical isomerism of the two parent hydrocarbon molecules.—E. W. L.

UNITED STATES PATENT.

Rubber; Method of Dissolving and Recovering —. G. A. L. Clift, Assignor to Robinson Bros., Ltd., West Bromwich. U.S. Pat. 805,903, Nov. 28, 1905.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Sodium Sulphide; Use of — for Unhairing Hides. W. Eitner. *Gerber*, 1905, 31, 349—351.

THE use of sodium sulphide, although advocated 35 years ago by the author, has only during the last ten years been generally adopted, and is specially favoured by tanners of heavy leather. The depilation can be done either by painting or by liming in pits. By painting the hair side with the paste prepared in the following way, unhairing can be effected in four hours:—One part of sodium sulphide is dissolved in 5 parts of hot water, and the solution is poured into milk of lime prepared by slaking 3 parts of lime with 15 parts of water. 1.0 per cent. of sodium sulphide, calculated upon the weight of the green hide, should be used. Pastes which will act even more quickly than this can be prepared, by dissolving small quantities of realgar in the sodium sulphide solution and mixing it with milk of lime. By taking 0.3—0.4 per cent. of sodium sulphide and mixing it in the proportions of 1 part to 10 parts of lime and 60 parts of water, a paste can be prepared which will remove the hair from skins in 15 to 20 hours.

When liming in pits, 0.3—0.4 per cent. of sodium sulphide (calculated upon the weight of green hide) is used, together with 2 parts of lime for each part of sulphide, as there is no advantage gained by adding more lime. The hides can be unhaired after two days.

A solution of sodium sulphide containing 3 parts in 100 of water destroys hair very rapidly, and unhairing can be effected after three to four hours. It was, however, found that by prolonged treatment of hides with this solution, say, for 24 hours, brittle leather resulted. The author found that the addition of a small quantity of lime to the sulphide solution considerably increased its unhairing property; he, therefore, advocates the use of an unhairing liquor prepared as follows:—Thirty kilos. of sodium sulphide are dissolved in 100 litres of hot water and 3—6 kilos. of slaked lime are added and well stirred up with the solution. A white precipitate is formed, which settles quickly; the clear liquor is drawn off and diluted with water to 10 hectolitres. The liquor is free from lime and should be of 1.021 sp. gr. or 3° B. when diluted. The hides are laid flat in a pit containing this liquor for one hour, and are then "horred" for one to one and a-half hours. The spent liquor is made up to 3° B. and used over again. The unhairing can be done effectively by drumming in a wash-wheel, or by brushing. The remaining operations do not differ from the customary ones. The suspender liquor should be slightly acid, and should contain mild tannins. This method of liming being more costly, economy has to be strictly observed, although the higher leather-weight, which is obtained by the use of this method, will alone compensate for the increased costs.

Sodium sulphide, as brought on to the market, varies much in strength; the author's results were obtained with the dry crystallised product.—F. K. K.

XV.—MANURES, Etc.

Soil; Effect of Plant Growth and of Manures on the Retention of Bases by the —. A. D. Hall and N. H. J. Miller. Roy. Soc. Proc. B., 1905, 77, 1—32.

ARABLE soils containing over 1 per cent. of calcium carbonate normally lose in the drainage water about 800 to 1000 lb. of calcium carbonate per annum. This loss is increased by the use of ammoniacal manures by an amount equivalent to the combined acid of the manure, but is diminished when sodium nitrate or organic *débris* is employed. A large portion of the bases of the neutral salts, provided by the soil for the nutrition of plants, is returned to the soil during the growth of the plant. The calcium oxalate and other organic calcium salts present in plant residues are converted into carbonate by bacterial action in the soil. This return of base to the soil by plant-growth and production of calcium carbonate by decay are sufficient to maintain neutral, soils which are poor in calcium carbonate, and to replace the bases which have been consumed in nitrification and similar changes.—F. F. B.

Nitrogen; Utilisation of Atmospheric —. O. N. Witt. *XII.*, page 27.

GERMAN PATENT.

Nitrogen Compounds from Alkaline-Earth Carbides; Process for the Manufacture of —. Ges. für Stickstoffdünger, G.m.b.H. Ger. Pat. 163,320, Nov. 1, 1901.

THE carbide is mixed with a chloride of an alkali, alkaline-earth or other metal, and ignited in an atmosphere of nitrogen. For example, 62 grms. of calcium carbide are mixed with 18.7 grms. of calcium chloride and heated to bright redness in an atmosphere of nitrogen. It is stated that 100 grms. of a product containing 19.3 per cent. of nitrogen are obtained in a short time.—A. S.

Scammony Root; Presence of Pentoses and Methyl-pentoses in —. P. Requier. *XXIV.*, page 44.

"Redo" [Calcium Hydrosulphite]; Employment of — in Sugar Factories and Refineries. E. Vasseur. Bull. Assoc. Chim. Sucr. Dist., 1905, 23, 541—545.

CALCIUM hydrosulphite or "redo" is soluble in water to the extent of 3—4 grms. per litre, and the solutions have a neutral or slightly alkaline reaction. This reducing agent is now prepared in a technically pure state, and used both in sugar factories and refineries, for decolorising juices, increasing the quotient of purity and reducing the viscosity of the syrups. In sugar factories this compound can be added to the diffusion liquors, to the carbonated juices, to the concentrated syrups, and to the spun syrups. In the last case, especially, the use of it enables larger quantities of molasses to be returned to the boiling syrups than is usually practicable, consequently third-jet products are dispensed with and a fully exhausted molasses is said to be produced. In sugar refining, "redo" is added to the melted syrup after defecation by lime; the temperature is then raised to 80° C. and the syrup is filtered. The action of the hydrosulphite is represented by the equation $\text{CaS}_2\text{O}_4 + \text{Ca}(\text{OH})_2 = 2\text{CaSO}_3 + \text{H}_2$. The calcium sulphite, being nearly insoluble at a high temperature, is readily removed by filtering hot. In sugar factories the quantity of the calcium hydrosulphite added to the juice after the second carbonation may, it is stated, be 20 grms. per hectolitre.—J. F. B.

Starch; Liquefaction of —. Mineral Compounds possessing Properties similar to those of the Liquefying Diastase of Malt. J. Wolff and E. Roux. *Comptes rend.*, 1905, 141, 1046—1048.

A PECULIAR modification of starch is prepared by treating 25 grms. of potato starch at the ordinary temperature with 50 c.c. of a 0.1 per cent. solution of potassium per-

manganate containing 10—15 per cent. of sulphuric acid or 6—7 per cent. of hydrochloric acid. After about two hours the liquid becomes colourless, the starch is filtered off, washed and dried at 30° C. A similar product is obtained by the use of bichromate or chlorine instead of permanganate. The modified starch apparently retains all its original properties; its 5 per cent. pastes, if made with distilled water, are scarcely less viscous than those of ordinary starch, and they are capable of undergoing reversible and diastatic coagulation in the ordinary way. But if the pastes of the modified starch be treated at about 70° C. with traces of a body possessing a basic reaction, e.g., with ammonia, the hydroxides or carbonates of the alkalis or alkaline-earths, or with secondary phosphates, they are immediately liquefied. The same effect is brought about by the basic matters in ordinary water if the latter be employed for making the paste. The liquefying action of these bodies at the ordinary temperature is almost nil; it increases rapidly with rise of temperature and reaches a maximum at 70°—75° C.; it differs from the liquefying action of malt by continuing at temperatures above 80° C. The liquefied starch pastes gradually revert to the gelatinous state when kept at the ordinary temperature, but the jelly so produced is readily soluble on heating and gives limpid solutions. The degree of liquefaction, the permanency of the liquefied solutions, and the solubility of the amylocellulose precipitated after saccharification, all depend on the intensity of the original oxidising treatment.—J. F. B.

XVII.—BREWING, WINES, SPIRITS, &c.

Seeds; Germination of —. J. Effront. Bull. Assoc. Chim. Sucr. Dist., 1905, 23, 508—522.

THE following additional points are incorporated, in a more complete paper, with those already dealt with (see this J., 1905, 1183). The author has studied the operation of malting from the distillery point of view, i.e., the production of maximum diastatic power. It is difficult, if not impossible, to combine the maximum saccharifying power with the maximum liquefying power in the same malt; and the author concludes that the liquefying power of the malt is a better measure of its value in practice than the saccharifying power. The determination of saccharifying power is complicated by the influence of foreign matters (such as salts and amino-acids) in the medium, and the results are not always a measure of the true quantity of diastase present. In order to avoid this influence, it is necessary to produce very profound saccharifications. For this purpose, varying quantities of malt were added to equal quantities of boiled starch and allowed to saccharify at 60° C for one hour; all the tests were

then fermented under equal conditions, and the yields of alcohol were determined. It was found that the quantity of a given malt necessary to produce a given quantity of alcohol was a function of the liquefying power of the malt, and bore no relation to its saccharifying power. The quantity of diastase developed is in direct relation to the time of floor treatment and to the development of the plumule. At 15° C., the time of germination should be at least 10 days, and the external plumule should have attained at least twice the length of the corn, for the production of the maximum quantity of diastase. A malt with a long plumule does not contain a maximum amount of diastase if the growth has been forced. On the other hand, a malt with a short plumule has not the maximum diastatic power even if the floor treatment has been very prolonged. Practically the whole of the diastase, both saccharifying and liquefying, remains in the corn itself; the migration of diastase into the radicles and plumules is insignificant.—J. F. B.

Yeast; Growth of — in Mineral Nutrient Media. T. Chrzaszcz. Cent. Bakt. [Abth. 2], 1904, 13, 144; through Z. ges. Brauw., 1905, 28, 825—826.

THE author prepared nutrient media containing sugar and mineral salts. A precipitate of calcium phosphate was formed, which in some cases was filtered off, and in other cases was allowed to remain. The unfiltered solutions were more favourable to the development of the yeast, especially when only a few cells were sown. Oxygen is favourable to the development. Traces of impurities in the salts employed, and also the use of distilled water, retard the growth of the yeast; sulphuric acid and strychnine salts are also unfavourable. The smaller the amount of phosphoric acid (or otherwise of lime and magnesia) in the solution, the worse is the development of the yeast. Different races of yeast vary as to behaviour in these solutions. The addition of calcium salts is only favourable when these are added in the form of the soluble phosphate; ferric chloride has no influence on the development of the yeast.—J. F. B.

Beer; Sarcina Sickness of —: Symptoms and Measures for Preventing. H. Will. Z. ges. Brauw., 1905, 28, 817—820, 833—836.

SARCINA sickness attacks pale beers more frequently than dark, but very seldom occurs in strongly hopped beers; the organisms exist in beer, as a rule, only in the pedococcus form. Sarcina sickness causes alterations in the odour and flavour of the beer, which may or may not become turbid. In rarer cases, changes in the colour of the beer and ropiness may be observed. A strong growth of sarcina in beer does not always produce sickness, hence the idea of varying degrees of virulence has arisen. The symptoms of the sickness nearly always make their appearance only in the later stages of the process of manufacture, e.g., in the lager cellar, the transport casks and bottles; the sickness is frequently accompanied by the separation of a gluten "haze." In all cases, the germs propagated in the brewery itself, being more or less acclimatised, are more dangerous than those introduced from outside. The first steps to be taken in dealing with the sarcina sickness are to ensure thorough cleanliness in all the above respects. Next, the predisposition of the beer may be reduced by brewing only thoroughly modified malt made from barley not too rich in protein, by allowing a more complete saccharification of the wort, aerating thoroughly and increasing the proportion of hops. The wort should be pitched at once with a sufficient quantity of a rapidly multiplying, highly attenuative yeast. The yeast should be well washed and as fresh as possible; it should be developed with strong aeration, and should be changed rather frequently. In the lager cellar, the beer should mature without disturbance or "frets," and at as low a temperature as possible. The addition of a small proportion of raw hops together with strongly hopped "Kräusen," and immediately closing the cask, will sometimes cure sarcina sickness if not too far advanced. In racking, filtering and bottling, scrupulous cleanliness must be exercised, and all losses of carbon dioxide must be prevented; attention should be paid to the condition of the filter and filtering pulp.—J. F. B.

Fermenting Liquids; Influence of Metals on —. III. L. Nathan, A. Schmidt and W. Fuchs. Centr. Bakt. [Abth. 2], 1905, 349; through Woch. f. Brau., 1905, 22, 704 (see also this J., 1904, 876 and 1905, 745).

IN working with yeast-propagating apparatus tinned internally, the fermentation proceeds more slowly, especially during the budding stage, and the yeast so obtained shows a modified granular structure, and possesses a lower fermentative power as compared with yeast grown in non-metallic vessels under similar conditions. The yeast propagated in metallic vessels frequently imparts an abnormal bitter metallic flavour to the beer fermented by it. These peculiarities generally disappear after the yeast has been used two or three times. The tin coating of the vessels tends to disappear somewhat rapidly. Fermentations in presence of iron give beers with a grey or black tint; tin and tinned iron change the brown colour of the wort to yellow during sterilisation, and produce a milky turbidity during fermentation; lead causes milkiness, and zinc imparts a dirty green shade to the liquid. Further experiments were made with the simultaneous presence of two metals, but the results were no worse than with one metal; the metallic couples behaved approximately like the alloys. Only glass appears to be entirely without influence on the fermentation, yield of yeast and appearance of the beer; gold and silver cause a small decrease in the yeast-crop; copper and nickel cause a darkening of the colour, whilst the other metals tend to turn the shade paler. Iron, tin, zinc, bronze, lead, aluminium and brass are to be regarded as powerful yeast poisons.—J. F. B.

Formaldehyde as a Disinfectant in the Brewery. H. Schnegg. Z. ges. Brauw., 1905, 28, 807—810, and 820—824.

AS the result of a large number of practical tests, the author concludes that formaldehyde is a most efficient disinfectant for general brewery use, and that it gives satisfaction when applied to pipes, whether of metal or rubber, wooden vessels, walls and floors. The solution should contain at least 0.5 per cent of formaldehyde, at which concentration it is cheap, and its odour is harmless. When applied after a thorough mechanical scouring with water, a duration of two hours' contact with a 0.5 per cent solution of formaldehyde is generally sufficient, although longer contact, up to 24 hours, is advantageous when possible. The action of the formaldehyde is so thorough, that a disinfection once a week is generally sufficient. Owing to the great capacity of formaldehyde for inhibiting growth, any serious accumulation of organisms is prevented, so that, after a long period of disinfection with formaldehyde, the pipes of the brewery become free from organisms. Continued use of formaldehyde produces no deterioration of metal, rubber, wood or tannin. In the case of pipes, the same solution of formaldehyde may be used at least twice, whilst in other cases, it may be used several times over without losing its disinfectant action.—J. F. B.

Alcohol in France for Industrial Purposes. D. Sidorisky. Bull. Assoc. Chim. Sucr. Dist., 1905, 23, 545—548.

THE total consumption of denatured spirits in France has risen from 374,698 hl. in 1903 to 423,561 hl. in 1904, in spite of a considerable rise in price. Of this increase, 27,712 hl. related to spirits for heating and lighting purposes.

The consumption of spirits for dyestuffs, varnishes, &c., has varied between the limits of about 13,000 and 19,000 hl. in the last 15 years; until the year 1903, the consumption of spirits for collodions, plastic masses and artificial silk never rose beyond 9750 hl., but, in 1903, it suddenly increased to over 20,000 hl., falling to 19,000 in 1904. In 1903, the quantity of spirits used for chemical and pharmaceutical products showed an increase of 50 per cent. over the previous year, rising to 12,944 hl., but falling again to 9041 hl. in 1904. The increase in consumption for others and explosives has been fairly continuous during the last 15 years; the quantity used for these purposes being 89,917 hl. in 1904. The quantity

of spirit issued free of duty for vinegar manufacture has not varied greatly during 15 years; in 1904 the consumption was 53,298 hl.—J. F. B.

Spirits and Brandies; Uniform Methods for Analysis of —. E. Barbot. XXIII., page 43.

ENGLISH PATENT.

Beer; Pasteurising — in Barrels. C. Thiel and Söhne, Lübeck, Germany, and H. Gronwald, Berlin. Eng. Pat. 17,419, Aug. 29, 1905.

THE apparatus consists of a metal beer barrel, which is completely filled with beer, and an expansion vessel or receiver, which is filled with carbon dioxide. These two vessels are connected with each other, the receiver being undermost, by means of special valved pipes and connections, which permit a free interchange of gas and liquid between the two vessels whilst preventing the escape of any gas. The combined apparatus is clamped in a frame and is subjected to the pasteurising treatment. After cooling, the apparatus is thoroughly agitated to promote the re-absorption of the carbon dioxide; it is then removed from the frame and placed with the barrel undermost. The beer thus runs from the expansion vessel, filling the cask, and the excess of gas collects in the receiver.

—J. F. B.

UNITED STATES PATENT.

Malt Decoctions; Process for Producing Tasteless Roasted —. M. Weyermann, Bamberg, Germany. U.S. Pat. 805,607, Nov. 28, 1905.

SEE Eng. Pat. 6796 of 1902; this J., 1902, 923.—T. F. B.

FRENCH PATENTS.

Still. Soc. Nordon Frères. Fr. Pat. 355,691, June 28, 1905.

THE still body 12 is constructed in one piece with the upper part of the furnace casing 2, the whole being supported by the trunnions 7, on the brackets 8, fixed to the lower part of the furnace casing 1. The upper part of the still 13 is made of such a shape that the contents are completely emptied when the still head 14 is removed, and the upper part of the furnace 2 along with the still 12 is tilted on the trunnions 7, by the handle 22. The upper coils 17 of the condenser have an inclination towards the still and the level of the cooling water in the condenser tank 16 can be adjusted by inclining the elbow pipe 20 attached to the overflow 21. If it is desired to obtain strong spirit, the pipe 20 is turned into the vertical position, and consequently the upper coils of the condenser being cooled, most of the aqueous vapour is condensed there and flows back to the still 12 through the pipe 15, whilst the alcohol

vapours pass on alone and are condensed in the lower part of the coil 18. If weaker spirit is wanted, the pipe 20 is turned down and the upper coils allowed to get warm, when the water vapour passes on with the alcohol vapours to the lower coils 18, where they are condensed together.

—W. H. C.

Wines, Brandies, Spirits and Liqueurs; [Electrical] Process for Ageing and Improving —. J. M. L. Desvignes. Fr. Pat. 350,279, Oct. 31, 1904.

A CONTINUOUS current of electricity is passed through the liquid to be treated, the positive electrode being placed in the liquid, whilst the negative electrode is separated therefrom by a porous membrane, which permits the passage of the current whilst preventing, as far as possible, the mixture of the liquids surrounding the two electrodes.—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(A.)—FOODS.

ENGLISH PATENTS.

Food for Animals [Peat and Molasses]; Manufacture of —. F. Livingstone, London. Eng. Pat. 27,597, Dec. 17, 1904.

TO prevent fermentation of mixtures of peat and molasses, the patentee adds from 0.5 to 1 lb. of salicylic acid to every ton of the mixture. Boric acid and other similar substances may be used instead of salicylic acid. A product is also claimed, consisting of a mixture of peat with a combination of cane molasses and beetroot molasses, with or without the addition of salicylic acid.—W. P. S.

Milk Powder; Manufacture of —. C. Haccius, Geneva, Switzerland. Eng. Pat. 27,718, Dec. 19, 1904.

THE milk is projected in the form of a fine spray on to the surface of a rotating drum heated to a temperature above 120° C. A number of simple jets or a single flat jet may be employed. The film of dry milk is removed from the drum by means of a scraper, the drum being rotated at such a speed that the film is removed within 10 seconds after the milk has been sprayed on to the drum. A longitudinal motion may be imparted to the scraper to increase its action on the surface of the drum.—W. P. S.

Milk, Cream, Casein and their Derivatives; Desiccation and Preservation of —. B. J. B. Mills, London. From P. Bévenot and E. de Neveu, Paris. Eng. Pat. 29,367, Dec. 31, 1904.

THE milk, &c., is projected upwards by means of an atomiser into a drying chamber through which a current of hot air is passed. The drying chamber consists of a cylindrical vessel, in which is placed a central heated tube surrounding the jet of the atomiser. The air which is blown through the chamber is previously heated to a temperature below 100° C., but sufficiently high to ensure pasteurisation of the milk. An opening is provided at the top of the chamber through which the air leaves, a plate or screen being placed below this opening to prevent the escape of any milk-spray. The dry milk falls in the form of a fine powder to the bottom of the chamber.

Pepsin Preparation. J. Altschul, Assignor to Act.-Ges. f. Anilinfabr., Berlin. U.S. Pat. 806,615, Dec. 5, 1905. See Fr. Pat. 355,560 of 1905; this J., 1905, 1249.—T. F. B.

FRENCH PATENT.

Threads and Sheets from the Protein Substances of Milk; Process of Making Textile. — H. Timpe. Fr. Pat. 356,508, July 28, 1905. V., page 16.

(B.)—SANITATION; WATER PURIFICATION.

UNITED STATES PATENT.

Water Purifier. P. Bastian, Grovenbroich, Germany. Assignor to Maschinenfabrik-Grovenbroich, Germany. U.S. Pat. 806,234, Dec. 5, 1905.

THE water to be purified is received in a circular vessel, which is surrounded by a second vessel, the upper edge of the circular partition common to both vessels being horizontal. The second vessel is divided by means of a movable radial partition into two chambers, one of which chambers discharges into a tank containing a supply of precipitant and the other into a heater. A constant percentage of the water issuing from the heater is separated and made to operate a tipping arrangement consisting of two buckets, which in their turn work a dipping vessel fitted in a lye tank. Means are provided for re-uniting all the separate portions of water, &c., and conducting them to a precipitating tank. The latter consists of a vertical cylinder surrounded by a series of conical guide-plates and enclosed by an outer wall, a valve at the bottom allowing the deposited solids to be removed.

—W. P. S.

FRENCH PATENTS.

Water; Process for the Purification of — L. Maiche. Fr. Pat. 350,264, Oct. 26, 1904. W.

THE water is passed through a vessel or filter filled with powdered sulphur, preferably flowers of sulphur. Any convenient form of vessel may be employed, and it is claimed that the sulphur destroys all bacterial life.

—W. P. S.

Water and other Liquids; Process and Apparatus for Destroying the Pathogenic Organisms in — P. G. Griffith. Fr. Pat. 356,946, Aug. 16, 1905. Under Int. Conv., Aug. 18, 1904.

XIX.—PAPER, PASTEBOARD, Etc.

Celluloid Goods; Liability of —, to fire. J. Bronn. Z. angew. Chem., 1905, 18, 1970—1977.

THE author gives an account of researches made by F. Gervais in the laboratory of the Ministry of Finance in St. Petersburg. Gervais' conclusions are as follows:—1. Celluloid wares, remaining in contact with a source of heat at 100° C., decompose spontaneously. 2. This decomposition is accompanied by evolution of heat, which may raise the temperature much above that of the original source of heat, but will not cause ignition of the goods. 3. The temperature may, however, rise high enough to cause the packing-paper to smoulder, and, in presence of air, to take fire. 4. Celluloid goods inflame only when brought into contact with a vigorously burning body. Smouldering wood, or a red hot wire or glass rod, will not inflame them.

In the course of the research, the ignition-temperature of various celluloid articles was determined at from 355° to 457° C.—J. T. D.

Wood Pulp Production of Norway. Bd. of Trade J. Dec. 21, 1905.

ACCORDING to the statistical report of the Norwegian Pulp-makers' Association, the unsold quantity of wood-pulp for 1905 was a very small one. The calculated total production is about 10,000 tons less than in 1904, and 60,000 tons less than in 1902. This decrease is due to the fact that several pulp mills have gone over to the production of paper. A further decrease of about 20,000 tons may be anticipated for the year 1906. The market is consequently very firm. [T.R.]

Starch, Glycogen and Cellulose. Z. H. Skraup and others. XXIV., page 43.

ENGLISH PATENT.

Paper; Apparatus [Beating-Engine] for Treatment of Fibrous Materials for Manufacture of — D. N. Bertram and S. Milne, Edinburgh. Eng. Pat. 1727, Jan. 28, 1905.

THE apparatus consists of two vertical chambers or chests, one constituting an up-take, and the other a down-take duct for the pulp. Between these two ducts, at the upper end, the beater-roll and bed-plate are supported, whilst at the bottom end is placed a circulating device which is also provided with toothed or cutting edges which chop up any large pieces of material which would tend to clog the device. The two vertical ducts are so strengthened as to carry the beating portion of the engine without further support, but the internal diameter of the up-take duct is made considerably smaller than that of the down-take duct, whilst the interior of both ducts may be suitably shaped and tapered so as to offer the minimum resistance to circulation.—J. F. B.

FRENCH PATENTS.

Paste-board; Process and Apparatus for Manufacture of — R. Kron. Fr. Pat. 356,998, Aug. 12, 1905.

A COMPOUND paste-board having one or both of its surfaces coated with an "art" or chrome composition is prepared by making two webs of paper on two independent machines placed end to end, so as to deliver their products at a common point. These webs of paper are partly dried before they arrive at the meeting point and the exterior surface of one or both of them is coated with the composition required. When the two webs meet each other, a cementing agent is applied, and the two webs are then pressed together and dried on a third set of drying cylinders.—J. F. B.

Silk; Process of Making Artificial — G. Dieth. Fr. Pat. 356,323, July 21, 1905. V., page 16.

GERMAN PATENTS.

Wood for Paper Manufacture; Process of Treating — E. Bergerhoff. Ger. Pat. 163,070, June 2, 1904.

COMMUNED wood is treated with water alone to prepare wood pulp for paper manufacture. The wood is moistened

F 2.

with water and steam is introduced, at a pressure of five atmospheres, for six to eight hours. It is stated that the temperature rises to about 125° C. The pulp thus produced is stated to be suited to paper making without further treatment of any kind.—T. F. B. *ibid.*

Cellulose Products Soluble in Ammonia: Process of Preparing——J. P. Beinberg, A.-G. Ger. Pat. 162,866, Sept. 29, 1900.

It is claimed that a "copper hydroxide cellulose," readily soluble in ammonia, is obtained by the action of alkalis on a mixture of cellulose and copper, or the mixture may be treated with a solution of copper sulphate, and an alkali chloride, or with ammonia and atmospheric oxygen. For example, a mixture of cotton and copper is wetted with water (100–150 per cent. of the weight of the cotton), and ammonia is either added as a solution, or the gas is passed over the mixture. The resulting blue mixture is said to be readily soluble in ammonia, giving highly concentrated cuprocellulose solutions.—T. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Sparteine, Hydroxides of Methyl-, Dimethyl- and Trimethylsparteinium. C. Mourcu and A. Valeur. J. Pharm. Chim., 1905, 22, 529–531.

The action of methyl iodide on sparteine has been studied with a view of elucidating the problem as to the molecular structure of the base. It was thought that the iodide would act, at least chiefly, on the nitrogen atom to which it is originally fixed as sparteine iodomethylate, and thus obviate the difficulty which arises from the presence of two nitrogen atoms in the molecule $C_{15}H_{26}N_2$.

Methyl-sparteine. Methyl-sparteinium Hydroxide.—The α -iodomethylate of sparteine was converted by means of silver hydroxide into methyl-sparteinium hydroxide. On heating this to 175° C. *in vacuo*, it is decomposed into a mixture of isomerides of the formula $C_{15}H_{26}N_2(CH_3)$, separable by fractional distillation *in vacuo* into fractions boiling between 171° and 175° C. under 11.5 mm., and with rotations between $[\alpha]_D^{20} = -16.67'$ and $-40'$ in absolute alcohol.

Dimethylsparteine. Dimethyl-sparteinium Hydroxide.—On leaving equal weights of methyl iodide and methyl sparteine in contact, at the normal temperature, for several days, and then heating on the water-bath for several hours, a reddish translucent mass was obtained. When this was dissolved in tepid water and treated with silver hydroxide, dimethylsparteinium hydroxide separated. This, when heated to 175° C. *in vacuo*, gave dimethylsparteine $C_{15}H_{24}N_2(CH_3)_2$.

Trimethylsparteinium Hydroxide; hemisparteine.—Dimethyl-sparteine was converted into iodomethylate, then into trimethyl-sparteinium hydroxide. This gave off trimethylamine even on distillation at ordinary pressure; on completing the distillation, the residue was heated to 200°–210° C., when abundance of trimethylamine was given off. At the same time an oily body, b.pt. 135°–153° C. under 13 mm. was obtained which responds to the formula $C_{15}H_{23}N$ and is, therefore, hemisparteine.

Methylsparteine, dimethylsparteine and hemisparteine are all unsaturated tertiary bases, which energetically reduce permanganate in acid solution. They are evidently not definite bodies, but mixtures of isomerides, the products of successive dehydration. These results obtained with sparteine are similar to those of R. Willstaetter and E. Fournau (Ber., 1902, 35, 1910; this J., 1902, 871) obtained with lupinine $C_{20}H_{31}ON$, and point to an analogous constitution of the two bases, which, moreover, are found in the same plant; since R. Willstaetter and W. Marx have shown lupinidine and sparteine to be identical.—J. O. B.

Prulaurenin: A Crystallised Cyanogenetic Glucoside from Cherry-Laurel Leaves. H. Hérissay. Comptes rend., 1906, 141, 959–961.

The author has extracted this glucoside from cherry-

laurel leaves. It crystallises in fine, flexible, colourless needles, has a slightly bitter taste, and melts at 120°–122° C. It dissolves readily in water, alcohol, or ethyl acetate, but not in ether. It is levorotatory ($\alpha_D = -52.7$). It is hydrolysed by emulsin, yielding dextrose, hydrocyanic acid, and benzaldehyde. It is thus ($C_{14}H_{17}NO_6$) isomeric with Fischer's amygdonitrile glucoside, and with Bourquelot and Danjou's sambunigrin.—J. T. D.

Essential Oils; Sicilian——J. C. Uinney and C. T. Bennett. Pharm. J., 1905, 75, 880–892.

Peppermint Oil.—Three samples of oil from Mitcham black peppermint plants, cultivated in Sicily, distilled in July, 1904, December, 1904, and July, 1905, had the following characters:—*July, 1904, oil*: Sp. gr. at 15° C., 0.908; $\alpha_D = -14^\circ$; total menthol, 40 per cent.; free menthol, 36.4 per cent.; esters as menthyl acetate, 4.8 per cent.; solubility, 1:4 in 70 per cent. alcohol. *December, 1904, oil*: Sp. gr. at 15° C., 0.920; $\alpha_D = -23^\circ$; total menthol, 70.5 per cent.; free menthol, 47.8 per cent.; esters as menthyl acetate, 20.4 per cent.; solubility, 1:2 in 80 per cent. alcohol. *July, 1905, oil*: Sp. gr. at 15° C., 0.906; $\alpha_D = -21^\circ$; total menthol, 41.6 per cent.; free menthol, 36.9 per cent.; esters as menthyl acetate, 6.0 per cent.; solubility, 1:3 of 70 per cent. alcohol. It is evident from these figures that the two specimens of oil distilled in July in successive years differ very slightly in characters, while the oil distilled in December has an abnormally high ester value. The results indicate the influence of climate, soil, and culture on the characters of the oil formed in the plant and confirm the observations of Charabot, that esters increase with the development of the green parts of the plant. This increase would appear also to be associated with slow growth.

Origanum oils.—*Sicilian origanum oil*, probably distilled from *Origanum creticum*, had the following characters:—Sp. gr. at 15° C., 0.920; $\alpha_D = \text{nil}$, or very slightly levogyre; phenols, 44 per cent., chiefly carvacrol; solubility, 1:2 of 80 per cent. alcohol, but not in 70 per cent. alcohol. This was compared with the following origanum and thyme oils from other sources. *Cyprian origanum oil*.—Sp. gr. at 15° C., 0.963; $\alpha_D = \text{nil}$; carvacrol 81.5 per cent. by volume; solubility in 70 per cent. alcohol, 1:2. *Trieste origanum oil*, probably distilled from *Origanum hirtum*.—Sp. gr., 0.940 to 0.980; α_D , slightly levogyre; carvacrol, 60 to 85 per cent. *Smyrna origanum oil*.—Sp. gr. at 15° C., 0.915 to 0.915; $\alpha_D = -3^\circ$ to -12° ; carvacrol, 25 to 60 per cent. *French thyme oil*.—Sp. gr. at 15° C., 0.905 to 0.920; thymol, 20 to 35 per cent. or more; solubility, 1:2 in 80 per cent. alcohol. This oil is derived from *Thymus vulgaris*. *Spanish thyme oil*, of doubtful botanical origin, sp. gr. 0.930 to 0.950; carvacrol, 50 to 70 per cent.; thymol, none; solubility, 1:3 in 70 per cent. alcohol. The antiseptic properties of the oils of origanum and thyme have been found by Chamberland and others to be practically identical.

Geranium oil.—The plants, grown on dry soil yielded only 0.07 per cent. of dark green oil; sp. gr. at 15°, 0.894; esters as geranyl tiglate, 35.6 per cent.; total geraniol, 71.9 per cent.; solubility in 80 per cent. alcohol, 1:2; insoluble in 70 per cent. alcohol. From the low yield the oil is not likely to acquire commercial importance, notwithstanding its fine quality.

Pennyroyal oil, distilled from *Mentha pulegium*, had the following characters:—Sp. gr. at 15° C., 0.927; $\alpha_D = +35^\circ$; pulegone, distilling between 212° and 220° C., 75 per cent.; solubility, in 70 per cent. alcohol, 1:2.

Lemon leaf oil.—Named "petitgrain citronnier." The oil is quite distinct in odour and characters from ordinary petitgrain oil derived from orange leaves. It contains a considerable amount of citral. Sp. gr. 0.873 at 15° C.; $\alpha_D = +26^\circ$; esters, 9.4 per cent.; "acetylisable constituents," 38.9 per cent.; aldehyde, chiefly citral, 29 per cent. Thirty per cent. of the oil, probably limonene, distils between 175° and 180° C. It is suggested that possibly this oil might prove to be a remunerative source of citral.

Nepeta oil.—The characters of the oil so named—sp. gr. 0.927 at 15° C.; $\alpha_D = +12^\circ$; alcohols (as menthol),

22.2 per cent.; esters (as menthyl acetate), 3.3 per cent.—are quite distinct from those of the oil of the American catmint, *Nepeta cataria*; or from those of the ground ivy oil, from *Nepeta glechoma*. The Sicilian oil may possibly be derived from *Mentha requienii*.—J. O. B.

Cinnamic Acid from Storax. E. Erlenmeyer, jun. Ber., 1905, 38, 3891—3892.

THE cinnamic acid prepared from storax gives a quantitative yield of brucine salt melting at 135° C. with not a trace of lower melting salts, and shows, in 5 per cent. solution, the ordinary dextro-rotation. On crystallisation from ether, synthetic cinnamic acid gives measurable crystals only with difficulty, whilst the acid from storax is obtained in large crystals having the same appearance as the acid prepared from the salt melting at 135° C. These observations are in accord with those of Simon (Annalen, 1839, 31, 265), who found that the cinnamic acid obtained from storax by means of sodium hydroxide, crystallises in a form quite different from that of the acid prepared by hydrolysing the styracin of storax. —T. H. P.

[*Saccharin Benzoyl Sulphonic Imide; Contribution to the Chemistry of —.* F. D. Chattaway. Chem. Soc. Proc., 1905, 21, 284.

WHEN chlorine is passed into a solution of saccharin in aqueous potassium or sodium hydroxide, a sparingly soluble substituted nitrogen chloride may be precipitated, or the solution may remain clear according as an equivalent quantity of caustic alkali or an excess, has been employed. In the latter case, on the addition of a mineral acid, a compound is precipitated which may be a sulphondichloroamino- or a sulphonmonochloroamino-acid, according as the chlorine has or has not been used in excess. When chlorine is passed into a solution of the sodium salt of saccharin, *o*-benzoyl-*N*-chlorosulphonic imide or chloroaminosaccharin is precipitated in accordance with the following equation:—

This readily dissolves in an excess of caustic alkali, forming a salt of *o*-sulphondichloroaminobenzoic acid, thus:—

the latter, when treated with an excess of chlorine, is converted into the corresponding salt of *o*-sulphondichloroaminobenzoic acid, thus:—

Both of the acids can be liberated from their salts as sparingly soluble crystalline bodies on addition of dilute mineral acids.

Allypin, Benzoyl-tetramethyldiamino-ethylidimethyl-carbinol Hydrochloride. [A New Anæsthetic.] O. Neustätter. Münch. Med. Wochenschr. 52, 2015. Pharm. J., 1905, 869.

ALLYPIN has been introduced as a substitute for cocaine, for producing local anæsthesia. It occurs in crystals, m. pt. 169° C., readily soluble in water. Its aqueous solutions may be sterilised by boiling for five or ten minutes, and without undergoing decomposition; they are neutral, and are not precipitated by moderate amounts of sodium bicarbonate.—J. O. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Explosions; The Pressure of —. Experiments on Solid and Gaseous Explosives. J. E. Potavel. Roy. Soc. Proc., 1905, 76A, 492—494.

THE author gives an abstract of his investigations on the rise of pressure which takes place during the explosion of gases such as a mixture of coal gas and air, and also of cordite. The measurements were made by means of a specially constructed manometer which recorded photographically on a revolving cylinder. The maximum pressures obtained with cordite are in close agreement with those given by Noble; and it appears that the rate at which the flame travels toward the centre of each particle of explosive is proportional to the pressure under which combustion takes place. The time required for complete combustion decreases with the diameter of the cordite, but the shape of the curve representing the rise of pressure remains unaltered. It follows, therefore, that even if the cordite were in the finest state of division, and the combustion became nearly instantaneous, the effect would be quite distinct from that of a detonation. When the surface of the explosion chamber is large compared with its volume, the diameter of the cordite has a marked influence on the maximum pressure obtained, a large diameter causing a considerable decrease. With long vessels wave action is frequently set up.

The rate of cooling of the gas is shown to depend essentially on the thermal conductivity of the vessel, not

on that of the gas; and with the massive vessels used, it was found to vary approximately in proportion to the square of the surface.—B. J. S.

Explosives; Researches on —. III. Supplementary Note. Sir A. Nohle. Roy. Soc. Proc. 1905, 76A, 512—514 (See also this J. 1905, 940.)

SINCE the author's paper was published, Holborn and Austin (Preuss. Akad. Wiss. Berlin, Sitz. Ber., 1905, 5, 175) have shown that the specific heat of carbon dioxide increases with rise of temperature, the increments gradually getting smaller. It is assumed from extrapolation that the specific heat at constant volume becomes constant at 1300° C., viz., 0.2111. The temperatures of explosion of cordite, M.D., and nitrocellulose powders have therefore been recalculated on this basis, and also from the pressure assuming the following law to hold:— $t = \frac{P - P_0}{0.00367 P_0}$

The values are given in the following table:—

Density of Charge.	Cordite. •		M.D.		Nitrocellulose.	
	Temp. from Pressure.	Temp. from Heat.	Temp. from Pressure.	Temp. from Heat.	Temp. from Pressure.	Temp. from Heat.
0.50	5275	5263	—	—	—	—
0.45	5090	5090	4713	4624	4305	3954
0.40	4902	4970	4494	4411	4007	3890
0.35	4710	4860	4200	4215	4030	3785
0.30	4480	4800	3920	4070	3320	3670
0.25	4165	4770	3585	3945	3060	3530
0.20	3838	4760	3240	3870	2835	3425
0.15	3490	4760	2890	3840	2680	3345
0.10	3140	4790	2530	3830	2520	3295
0.05	2775	4800	2160	3880	2400	3255

It will be observed that, although for high densities the temperatures obtained by both methods agree fairly well, the values for low densities show marked discrepancies. This is probably due to the low rate of burning with rapid cooling, but the author also suggests that the carbon dioxide and aqueous vapour dissociate at low pressures, but cannot at higher pressures.

Substances such as carbon, platinum, tantalum, &c., when placed in the charge, were all fused.—B. J. S.

Powder; Process of Making Smokeless —. G. W. Gentiou and R. S. Waddell, Peoria, Ill. U.S. Pat. 806,131, Dec. 5, 1905.

NITROCELLULOSE, whilst being agitated, is treated first with jets of compressed air to break it up into porous grains, and then with a solvent in addition to the compressed air, to uniformly gelatinise the grains. After this treatment, heated air under pressure and at a comparatively low temperature is forced into the mass to expel the excess of solvent and to dry the grains.—A. S.

Powder; Smokeless —. R. D. Peck, Danville, Wis. U.S. Pat. 806,564, Dec. 5, 1905.

THIS powder is composed of granulated sugar (14 parts

by weight), potassium nitrate (4 parts), powdered potassium chlorate (4 parts), magnesium oxide (1 part) and "water (6 parts)."—A. S.

FRENCH PATENTS.

Priming Compositions and Charges for Shells and Torpedoes; Process of Preparing —. C. Claessen. Fr. Pat. 355,695, June 28, 1905.

THE detonating and explosive power of priming compositions for detonators and charges for shells and torpedoes is considerably increased by using tetranitromethylaniline or tetranitroethylaniline instead of picric acid or trinitrotoluene.—T. F. B.

Dynamite; Process for the Preparation of a Fire Damp —. C. E. Bichel, Germany. Fr. Pat. 356,845, July 10, 1905.

IT is claimed that a dynamite which has a low velocity of detonation, is easy to use, and gives off inoffensive products of combustion, may be prepared as follows:—An intimate mixture (about 80 parts) is made of ammonium nitrate, potassium perchlorate, and sodium chloride, the proportions of each being subject to variation at will. To this there are added 6—10 parts of trinitrotoluene dissolved in 4—10 parts of nitroglycerin or dinitroglycerin, and finally a small quantity of starch, powdered wood, or flour in order to facilitate the absorption of the nitroglycerin. The resulting explosive is stated to be easy of manipulation, and insensitive to shock, and is very suitable for use in presence of fire-damp.—B. J. S.

Explosives; Process for Modifying the Velocity of Detonation of —, so as to diminish their Bursting Effect. C. E. Bichel, Germany. Fr. Pat. 356,864, Aug. 2, 1905.

IT is possible to vary the velocity of detonation of explosives by altering their state of aggregation; thus, trinitrotoluene when compressed so as to have a sp. gr. of 1.55, gives a velocity of 7185 metres per sec., but in the form of grains of 2.6 mm diameter gives only 4470 mm. per sec. In actual practice the explosive may be utilised in the form of grains with air interstices or surrounded by powdered charcoal, graphite, aluminium powder, shellac, &c.

XXIII.—ANALYTICAL CHEMISTRY.

INORGANIC—QUANTITATIVE.

Sulphuric Acid; Determination of —, by Barium Chloride, in presence of other Substances. G. Lunge and R. Stierlin. Z. angew. Chem., 1905, 18, 1921—1930.

THE authors have examined the influence of various substances said to affect the accuracy of the determination of sulphates by precipitation with barium chloride. Their conclusions are as follows:—

1. *Copper.* When present in pyrites, even in considerable amount, copper introduces no error into the determination of sulphur when this is carried out exactly according to Lunge's directions. 2. *Zinc* in small proportion, as, for example, in zinciferous pyrites, does not affect the sulphur determination; but in larger proportion, for example in blendes, the results are always too low, from the solubility of barium sulphate in the ammonium salts necessary to hold the zinc in solution. The modification of the method suggested by Hintz and Weber (see below) gives accurate results in presence of zinc, through the compensating error of co-precipitated barium chloride. 3. The authors confirm a statement of Hintz and Weber, in a paper shortly to be published, that, in presence of salts of potassium, sodium, or ammonium, the barium sulphate precipitate always contains sulphate of the alkali metal. In the case of ammonium sulphate, this is vola-

tillised on ignition; in the other cases the alkali sulphate is weighed as barium sulphate. In any case, therefore, the precipitate is too light, and the sulphur result in consequence too low. Hintz and Wober find that if the barium chloride solution be added at once, instead of gradually, the error introduced by the co-precipitation of barium chloride with the sulphate almost exactly compensates the loss due to the cause just mentioned, so that the sulphur calculated from the weight of the crude barium sulphate precipitate agrees very accurately with that actually present. The authors, therefore, propose to modify Lunge's directions for precipitation, in the determination of sulphur in pyrites, as follows:—20 c.c. of 10 per cent. barium chloride solution are diluted with 100 c.c. of water, heated to boiling, and poured rapidly into the solution to be precipitated.—J. T. D.

Nitric and Nitrous Acids: Determination of —. J. Meisenheimer and F. Heim. Ber., 1905, 38, 3834—3837.

THE determinations are based respectively on the reactions:—

For nitrites, the slightly alkaline solution containing 0.1–0.2 gm. of nitrite, is introduced into a 50 c.c. flask, the stopper of which carries a tube for the introduction of a current of carbon dioxide, a delivery tube with drawn-out end, and a funnel. The drawn-out end of the delivery tube is placed in a 12 per cent. solution of sodium hydroxide, and carbon dioxide is passed through the apparatus till all air is expelled, say, for ten minutes. The stream is slackened, a measuring tube filled with sodium hydroxide solution is placed over the end of the delivery tube, and by means of the funnel (the tube of which has been previously filled with water) there are added, first, 10–15 c.c. of 5 per cent. solution of potassium iodide, and then, gradually, an equal volume of dilute hydrochloric acid. When the evolution of gas slackens, the flask is heated by a small flame to incipient boiling, and the residual nitric oxide driven over by the stream of carbon dioxide, increased for that purpose. When the volume of gas in the audiometer ceases to increase, the tube is removed, well shaken, immersed in a levelling vessel, and the volume of gas read.

If nitrates are to be determined in the residue, another measuring tube is placed in position, and 10–20 c.c. of concentrated ferrous chloride solution, rendered strongly acid by hydrochloric acid, are introduced through the funnel. The operation is concluded exactly as in Spiegel's modification of the Schulze-Tiemann method (this J., 1890, 899).

This method is rapid, allows of determining both nitrous and nitric acids in the same liquid, and gives in each case a direct determination.—J. T. D.

Nitrous Acid: Determination of —. F. Raschig. Ber., 1905, 38, 3911–3914.

THE author considers the sulphanilic acid method and the permanganate method of determining nitrous acid to be the best and most convenient where they can be applied; but in some cases, where for example nitrous acid and hydroxylamine temporarily exist together, those methods are not applicable, and in such cases he has used the reaction applied by Meisenheimer and Heim (see preceding abstract). He prefers, however, to titrate the iodine rather than to measure the nitric oxide. The solution (which must not be acid), about 100 c.c. contained in a 200 c.c. conical flask, is placed under the thiosulphate burette, 5–10 c.c. of 10 per cent. potassium iodide solution are added, and a stream of carbon dioxide is led through by a tube reaching to the bottom of the flask. After two to three minutes, about 1 c.c. of N/10 sulphuric acid is poured down the side of the tube, and after two minutes more, the titration is carried out, the thiosulphate solution being also allowed to glide down the side of the tube. The flask must not be taken up and shaken; the gas-bubbles ensure the mixture of the liquids, and the surface of the liquid is thus never exposed to air, which of course

would, on mixing with the escaping nitric oxide, lead to errors in titration. Titration must not be begun too early, or too much thiosulphate will be needed; the author thinks that, on acidifying, nitrosyl iodide NOI, is first formed, and that this requires time to decompose.

In using the permanganate method, the author pours the solution to be tested into N/10 permanganate solution, taking care that at least 20 per cent. excess of the latter be present, then acidifies (if necessary), and after two minutes, the reaction on the nitrous acid is complete. He then adds 5 c.c. of 10 per cent. solution of potassium iodide, which instantaneously dissolves any precipitate of manganose peroxide that may have formed, and titrates with thiosulphate.—J. T. D.

Bismuth: Determination of —, and its Separation from Copper, Cadmium, Mercury, and Silver. A. Staehler and W. Scharfberg. Ber., 1905, 38, 3882–3889.

BISMUTH can be accurately determined by precipitation as phosphate, even in presence of hydrochloric acid, provided a sufficiency of sodium phosphate be added to substitute phosphoric for the hydrochloric acid. The bismuth solution, containing 0.1–0.2 gm. of bismuth, is diluted to 300–400 c.c., and heated to boiling, any precipitate of basic salt being redissolved by cautious addition of nitric acid. Boiling 10 per cent. solution of trisodium phosphate (the disodium salt may be used, but in acid solutions so much of it may be needed as to make an inconveniently large bulk of liquid) is now gradually added, stirring constantly. An excess of sodium phosphate does no harm, so long as it is not sufficient to produce alkaline reaction in the liquid. The boiling and stirring are continued for a few minutes, and the precipitate allowed to settle so far that the completeness of precipitation can be tested by adding more of the precipitant. When complete, the hot liquid is filtered through a Gooch crucible (the filtrate being again tested with the precipitant) and washed with 1 per cent. nitric acid containing a little ammonium nitrate (the washing must not be too long continued, or the precipitate has a tendency to become colloidal), dried at 120° C., ignited over a good flame for five or ten minutes, and weighed as BiPO₄.

Separation from Copper.—The bismuth is precipitated from the mixed solution exactly as above, and the copper in the filtrate thrown down as sulphide and weighed as cuprous sulphide. In presence of chlorides, electrolysis was found not to yield good results.

Separation from Cadmium.—The bismuth is precipitated as above; then, if chlorides be absent, the solution is rendered ammoniacal, a little potassium cyanide added, and the cadmium determined electrolytically. If chlorides be present, the cadmium is precipitated as sulphide, the sulphide washed, dissolved in weak nitric acid, potassium hydroxide in excess and potassium cyanide added, and the solution electrolysed.

Separation from Mercury.—After precipitating the bismuth, hydrochloric acid is added, followed by excess of ammonia. If there be any precipitate, more hydrochloric acid and ammonia are added, and so on, till the amount of ammonium salt present suffices to keep the mercury dissolved in presence of excess of ammonia. The solution is then heated to boiling and saturated with hydrogen sulphide. In five or ten minutes the precipitation is complete, and the sulphide, quite free from excess of sulphur, is filtered through a Gooch crucible, washed with hot water, alcohol, and ether, dried at 105° C., and weighed.

Separation from Silver.—The bismuth is precipitated as above, and the silver in the filtrate determined either as chloride or by titration with ammonium thiocyanate.—J. T. D.

Bismuth: Determination of —, and its Separation from the other Heavy Metals by Precipitation as Phosphate. H. Salkowski. Ber., 1905, 38, 3943–3944.

THE author many years ago suggested this as an accurate method of determining bismuth, and has lately, with his pupils, taken up the matter again. They find that satisfactory separations from all the heavy metals can be

effected in this way, but that hydrochloric acid and chlorides interfere. Details of the methods are not given.

—J. T. D.

Silicon; Determination of — in Presence of Silica.
M. Philips. *Z. angew. Chem.*, 1906, 18, 1969—1972.

THE older methods of determining silicon in presence of silica, all involving ignition of a mixture of the two substances in the air, and treatment of the residue with hydrofluoric acid, are inaccurate, for the author has shown that silicon, even at low red heat, absorbs oxygen from the air fairly rapidly, and that it is sensibly attacked and volatilised by hydrofluoric acid. His method consists in dissolving the silicon in potassium hydroxide solution, and measuring the hydrogen evolved ($\text{Si} + 4\text{KOH} = \text{K}_2\text{SiO}_3 + 2\text{H}_2$), then determining the total silica, and calculating by difference the silica existing as such. The mixture, powdered extremely fine, is introduced into a small flask containing 30 per cent. potassium hydroxide solution, and standing in a water-bath at the temperature of the air. The flask is then connected with the upper three-way stopcock of a 200 c.c. Bunte burette, the cock being left open to the air for a few minutes till the temperature throughout is uniform. Connection to the burette is then made, the water-bath removed, and the flask heated gently over a flame till all silicon is dissolved. Then the bath is replaced, the whole allowed to regain the temperature of the air, the levels adjusted, and the volume of the gas read. The solution in the flask may be evaporated down with hydrochloric acid to determine the total silica; but as the alkali may dissolve silica from the glass, it is safer to fuse another portion of the substance with alkali carbonate and nitrate, and determine the total silica in that. —J. T. D.

Oxygen; Determination of — in Copper. L. Archbutt. *Analyst*, 1905, 30, 385—394 (this J., 1900, 1148).

It was stated by Dickson (this J., 1905, 638) that in order to expel the whole of the oxygen by heating copper to redness in hydrogen, it was essential to have the metal in a very fine state of division. The author, however, finds that the thickness of the copper has little, if any, influence upon the accuracy of the method, but that it chiefly affects the time required for a determination. Thus closely concordant results (0.17 to 0.18 per cent.) were obtained in the determination of oxygen in copper whether in the form of strips $\frac{1}{8}$ to $\frac{1}{4}$ in. in thickness, in fine turnings and sawings, or in rough $\frac{1}{4}$ in. cubes, the time required for the strips being two hours, and for the cubes five hours. Similarly a solid copper cylinder yielded the whole of its oxygen when heated to redness for nine hours in a current of hydrogen in a combustion tube of Jena glass. In the case of copper containing an unusually high percentage of oxygen (over 0.2 per cent.), the turnings yielded 0.224 to 0.226 per cent., whilst a cylinder $\frac{3}{8}$ in. in diameter gave 0.21 per cent. after being heated for eight hours, or only $\frac{1}{2}$ of the difference found by Dickson when working with wire 0.035 in. in diameter. The cylinder, when broken in the vice, had the same appearance from the core to the outside edge of its fracture. Copper deoxidised in hydrogen is very brittle, and frequently shows fissures on its outer surface. It also shows a considerable amount of expansion—as much as $\frac{1}{8}$ in. in the case of a cylinder of $\frac{1}{4}$ in. diameter. Examined under the microscope the surface fissures are seen to extend some way into the interior, passing between the crystalline grains, which, it is stated, increase in size during the annealing in hydrogen, whereas the junctions between them are loosened. Hence it is not surprising that the copper becomes brittle, nor that the whole of the oxygen is gradually expelled from the interior of a thick piece of the metal. —C. A. M.

Chlorine; Analysis of Electrolytic —. F. P. Treadwell and W. A. K. Christie. *Z. angew. Chem.*, 1905, 18, 1930—1934.

THE analysis of electrolytic chlorine consists practically in determining actual chlorine and carbon dioxide. The method formerly proposed by Treadwell (absorption of a measured volume of the dried gas by 5 per cent. solution

of sodium hydroxide, determination of hypochlorite by N/10 arsenious oxide, calculation of the corresponding volume of chlorine, and subtraction from the total to get the carbon dioxide) gives results always 0.7—0.77 per cent. too low, from formation of chlorate; and the method of Adolph (absorption as above, destruction of hypochlorite by hydrogen peroxide, and titration or measurement of the carbon dioxide) is difficult to work, as the hydroxide must be absolutely free from carbonate, whilst that of Offerhaus (absorption as above in one burette, reaction of gas in another burette on potassium iodide and titration of liberated iodine) requires two burettes, and is costly where many determinations must be made, from the amount of potassium iodide used. The method now proposed consists in absorbing the chlorine in solution of alkali arsenite free from carbonate, and then the carbon dioxide by alkali hydroxide. The arsenite solution is made by dissolving 4.95 grms. of arsenous oxide in dilute potassium hydroxide solution, adding phenolphthalein and exactly neutralising with sulphuric acid, and diluting to a litre. The chlorine is allowed to stream through the burette F from below, till all air is displaced, cock E is closed, then cock H, and the barometer and temperature of the surrounding water are read. D is now filled with distilled water, which is allowed to run out at C, so as to displace all air or chlorine from the rubber tube or B; then 100 c.c. of the arsenite solution are delivered into D and allowed to enter the burette, the complete absorption of the chlorine being aided by shaking. Next, 10 c.c. of strong potassium hydroxide (1:2) solution are placed in A, and cautiously drawn down into the burette and well shaken. The levels are adjusted, and the volume of the unabsorbed gas, the barometer, and the temperature, are read. The liquid from burette and levelling-tube is now run into a conical flask, and the apparatus thoroughly rinsed into the flask; to the liquid in the flask are successively added phenolphthalein, hydrochloric acid to neutrality, and 80 c.c. of solution of sodium bicarbonate (40 grms. per litre), and the unoxidised arsenite is titrated with N/10 iodine solution and starch. From the weight of chlorine thus determined, its volume is calculated (1 c.c. of N/10 solution = 0.003545 grm. of chlorine = 1.1015 c.c. at N.T.P.), and the difference between this and the total volume of gas absorbed, gives the carbon dioxide. Experiments with pure chlorine and with known mixtures have shown that the method is accurate, and that no chlorate is formed.

The authors have also devised a modification of Offerhaus' method, using only one burette—the same apparatus as already described. The chlorine is absorbed by 5 per cent. solution of potassium iodide, then the carbon dioxide by 10 c.c. of potassium hydroxide as above, and

the total volume of absorbed gas determined. The excess of hydroxide converts the liberated iodine into iodide and iodate; and when the liquid from the apparatus is now run into a beaker containing 10 c.c. of strong hydrochloric acid, the iodine is again liberated and is titrated with thiosulphate. The results are accurate, but the method presents no advantage over the arsenite method.—J. T. D.

ORGANIC—QUANTITATIVE.

Picric Acid Additive Compounds; Determination of —. F. S. Sinnatt. Chem. Soc. Proc., 1905, 18, 297.

KNECHT and Hibbert's method (this J., 1903, 762) for the determination of picric acid by means of titanous chloride has been found to be applicable to other picrates, and also to picric acid additive compounds.

Twenty-five c.c. of a solution of 0.200 gm. of naphthalene picrate in 250 c.c. of alcohol were titrated with titanous chloride, and gave 99.49 per cent. of naphthalene picrate. Pyridine and strychnine picrates yielded 100.19 and 99.69 per cent. respectively.

In many cases it is convenient to dissolve the picrate in hydrochloric acid. The method has been applied to the estimation of naphthalene in coal gas; the naphthalene picrate is separated by the usual process (Colman and Smith, this J., 1900, 128), washed, dissolved in a small volume of alcohol, and titrated with titanous chloride. If a standard solution of picric acid be used in the wash-bottles, the filtrate and washings may also be titrated. The results compare with those obtained by Colman and Smith's method.

Brandies and other Spirits; Uniform Methods for Analysis of —. E. Barbet. Ann. Brass et Dist., 1905 [19]; through Z. Spiritusind., 1905, 28, 466—469.

THE following methods have been selected by the author in conjunction with other chemists as the basis of a general agreement in the analysis of spirits.

Acidity.—The determination of the total free acidity is important as a preliminary to the determination of the esters. 100 c.c. of the spirit should be diluted to a strength of 50 per cent. of alcohol and titrated with standard calcium succinate solution (100 c.c. = 1 gm. of acetic acid) using litmus as an indicator. The neutral tint should be established by comparison with a mixture of the same quantities of litmus and neutral distilled water.

Esters.—The saponification should be effected by means of calcium succinate solution, which does not resinify the aldehydes; the following points are of importance:—The flask should be of hard glass, and connected to the reflux condenser by ground joints, without cork or rubber; three times the theoretical quantity of alkali should be used; the sample should not contain more than 50 per cent. of alcohol and should be boiled slowly for two hours. Volatile bases should be absorbed in a Will's apparatus at the upper end of the condenser. Coloured spirits must be diluted to a strength of 20 per cent. of alcohol, and distilled before saponification.

Aldehydes.—Three colorimetric methods are available: Rosaniline-bisulphite, *m*-phenylenediamine, and quinol (hydroquinone-) sulphuric acid. Preference is given to the last:—2 c.c. of the sample are mixed with 1 c.c. of the purest sulphuric acid, and 0.02 gm. of powdered quinol is added. A scale of standards is prepared from pure aldehyde-ammonia and matched by dyed gelatin.

Higher alcohols.—Rocques' method:—The spirit is diluted so as to contain 50 per cent. of alcohol; the aldehydes are destroyed in 100 c.c. of the product by boiling with *m*-phenylenediamine hydrochloride; exactly 75 c.c. are then distilled off. 10 c.c. of the distillate are mixed with 10 c.c. of sulphuric acid monohydrate (H_2SO_4) and the mixture is heated in a calcium chloride bath at exactly 120° C. for one hour. The coloration so obtained is compared with that developed by isobutyl alcohol under similar conditions. If the results are to be expressed in terms of amyl alcohol they must be multiplied by 1.6.

Furfural is determined colorimetrically by aniline acetate; the furfural is no guide to the origin of the spirit.—J. F. B.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Lithium; Iodomercurates of —. A. Duboin. Comptes rend., 1905, 141, 1015—1018.

ON cooling a hot saturated solution of mercuric iodide and lithium iodide, of sp. gr. 3.28, needle-shaped crystals were obtained of the composition $2\text{LiI} \cdot \text{HgI}_2 \cdot 6\text{H}_2\text{O}$. The crystals were very dense (sp. gr. 3.26), readily decomposed by water, soluble in many alcohols and esters, in formic and acetic acids, aldehyde, acetone, &c., but not in benzene or methyl iodide. The mother liquor at a still lower temperature deposits large prisms of $2\text{LiI} \cdot \text{HgI}_2 \cdot 8\text{H}_2\text{O}$, very soft and readily melted, especially in presence of traces of water, and having, generally, similar solubilities to the other salt.—J. T. D.

Bromine Fluoride. P. Lehan. Comptes rend., 1905, 141, 1018—1020.

BROMINE and fluorine combine at the ordinary temperature with evolution of heat, forming a compound of the formula BrF_3 . This is a colourless liquid, freezing to a solid, which melts again at about 4° C. It reacts on silicon in the cold, producing vivid incandescence, and its reactions on most other elements and many compound substances resemble those of fluorine in their vigour. —J. T. D.

Starch, Glycogen and Cellulose. Z. H. Skraup and others. Monatsh. f. Chem., 1905, 28, 1415—1472.

THE authors have studied the action of acetic anhydride saturated with gaseous hydrogen chloride on three representative polysaccharides; starch, glycogen and cellulose. They have endeavoured, by determinations of the minimum stoichiometrical ratios in which chlorine enters into the chloroacetylated derivatives so obtained, to assign minimum values for the molecular weights of these colloid carbohydrates, on the assumption that combination takes place in the first instance, without degradation of the aggregate, an assumption not wholly verified by the experimental results. The carbohydrates were suspended in acetic anhydride, the liquid was saturated at a low temperature with hydrogen chloride, and the mixtures were allowed to remain in contact for various lengths of time. A large number of chloroacetylated products have been isolated and purified by fractional solution and precipitation. These products were also converted into the corresponding acetyl compounds by replacing the chlorine atom by acetyl through the action of silver acetate. These acetates, on saponification, all proved to be triacetates on the C_6 unit for the three polysaccharides; the saponified residues were also examined as to the relation they bore to the parent substances. The following chloroacetyl derivatives are those which are regarded as being definite individuals with the closest approximation to the state of molecular aggregation of the original carbohydrates and as possessing 1 atom of chlorine in combination with each aggregate:—(1) From soluble starch, 0.268 per cent. of chlorine, indicating a molecular weight of $7440 = (\text{C}_6\text{H}_{10}\text{O}_5)_{145-50}$ for soluble starch; (2) from glycogen, 0.15 per cent. of chlorine indicating a molecular weight of $16350 = (\text{C}_6\text{H}_{10}\text{O}_5)_{190}$ for the saponified carbohydrate which was probably a degradation product of glycogen; (3) from cellulose, 0.36 per cent. of chlorine, indicating a molecular weight of $5508 = (\text{C}_6\text{H}_{10}\text{O}_5)_{64}$ for the saponified carbohydrate, regarded as being nearly equivalent to the original cellulose.

Longer periods of action gave chloroacetylated derivatives of degradation products of the parent carbohydrates, with percentages of chlorine increasing as the molecular aggregates became more simple. In the case of starch, chloroacetyl derivatives of erythro-dextrin ($\text{C}_6\text{H}_{10}\text{O}_5$), maltose and finally glucose were obtained. In the case of cellulose, a reaction lasting 14 days yielded a chloroacetyl derivative of cellobiose which is fully described.—J. F. B.

Scammony Root; Presence of Pentoses and Methyl-pentoses in —. P. Requier. J. Pharm. Chim., 1905, 22, 540—542.

In addition to saccharose, previously recorded (this J., 1905, 1246) as a constituent of scammony root, the presence of pentoses and methyl-pentoses is now established.

Saccharine constituents of fresh root.—These, calculated on the dry root, are:—Reducing sugars, as dextrose, 2.70 per cent.; saccharose, 6.80 per cent.; methyl-pentose, 0.95 per cent.; pentose, traces.

Saccharine constituents of dried root.—Reducing sugars as dextrose, 1.11 to 1.81 per cent.; saccharose, 2.08 to 3.30 per cent.; methyl-pentose, 0.226 to 0.253 per cent.; pentose, 0.05 to 0.065 per cent.—J. O. B.

Trade Report.

NEW ZEALAND; EXPORT TRADE OF —.

Bd. of Trade J., Dec. 28, 1905.

In the following table are given the values of exports of certain articles from New Zealand in the years ended Sept. 30, 1904 and 1905:

	Year ended 30th September	
	1904.	1905.
	£	£
Wool	4,331,000	5,542,000
Tallow	371,000	345,000
Butter	1,360,000	1,413,000
Sheep skins	496,000	465,000
Gold	2,052,000	2,035,000
Kauri gum	542,000	508,000
Timber	247,000	310,000

AUSTRALIAN CUSTOMS DECISIONS.

Bd. of Trade J., Dec. 21, 1905.

Decisions have been rendered by the Commonwealth Department of Trade and Customs, fixing the rates of import duty on the following substances: Algin (as glue, gelatin), 20 per cent. *ad valorem*; black-lead and plumbago in bulk, free; colours, soluble water, 20 per cent.; manures, including ammonium sulphate and phosphate rock, free; neutrex (cocoa butter substitute), 1d. per lb.; levulose (as glucose), 8s. per cwt.

NORWAY; CUSTOMS TARIFF OF —.

Further portions of the new customs tariff of Norway appear in the issues of the Board of Trade J. for each week, the concluding portion being in the issue for Dec. 14 last. Each of these numbers may be obtained from Messrs. Wyman and Sons, Fetter Lane, E.C. Price 1d.

SWITZERLAND; TRADE OF —.

For. Off. Ann. Series, No. 3520.

The value of the total imports of mineral products amounted to 3,499,000L., the share of the United Kingdom in these imports being only a small one (29,600L., of which 22,000L. was for coals). The value of coals imported from all countries amounted to 1,861,000L. (an increase of 122,000L. on the imports of 1903), of which Germany supplied 80 per cent.

The total imports of druggists' sundries, chemicals and colouring materials in 1904 amounted to 1,715,800L. (an increase of 68,800L. on the imports of 1903), of which 1,563,900L. was for manufactured chemical products.

The increase was principally in drugs, alcohol, anthracene and benzoin, sulphate of iron, copper and zinc, and sulphuric ether. The total imports from the United Kingdom amounted to 66,700L. The principal imports from all countries, together with the share of the United Kingdom, were as follows:—

Articles.	From—	
	All Countries.	United Kingdom.
	£	£
Drugs	125,500	5,800
Anthracene, benzoic acid, benzene, carbolic acid, &c.	99,400	4,500
Aniline colours	66,300	400
Aniline	65,800	1,000
Pharmaceutical preparations	52,600	4,800
Sulphate of iron, copper and zinc	49,800	15,900
Arsenical acid	46,700	4,500
Starch and dextrin	39,600	1,000
Caustic potash and caustic soda	35,900	2,600
Varnishes (not oil)	33,400	9,500
Stearine	29,000	3,000
Boracic, pure carbolic, phosphoric acids	27,500	900
Alkaloids	23,900	1,400
Extract of quinine and refined camphor	22,600	700
Bromide, iodine, carbonate of magnesia, &c.	14,000	2,300
Perfumes and cosmetics	13,900	600
Colouring materials	259,200	1,800

The total imports of varnishes in 1904 amounted to 33,400L., of which the United Kingdom supplied 9,500L., or an increase of 500L. on the preceding year. The principal supply came from Germany, representing a value of 14,500L.

The total import of oils, soaps, and fats in 1904 amounted to 546,000L., or a decrease of 45,000L. on the imports of the previous year. This decrease is accounted for mainly by the reduced imports of oils. The principal articles imported from all countries and from the United Kingdom were as follows: Various oils and liquid greases, 117,000L. (from the United Kingdom, 13,900L.); linseed oil, 72,000L. (United Kingdom, 3,000L.); ordinary and scented soaps, 42,400L. (United Kingdom, 1,700L.); candles, 2,200L. (United Kingdom, 500L.).

The imports of food articles amounted to 13,449,000L., as against 12,739,000L. in 1903; the imports included spirituous liquors, 35,000L.; and extract of meat, 21,000L.

The United Kingdom continues to be Switzerland's principal market for her manufactured goods, and in 1904 she took 21.9 per cent. of the Swiss exports, including ironware and machinery, 189,800L.; condensed milk, 695,800L.; chocolate, 451,600L.; pharmaceutical preparations, chemicals and colouring materials, 146,700L. The total export of chemicals from Switzerland in 1904 was valued at 1,375,000L.

New Books.

ELEMENTS OF QUANTITATIVE ANALYSIS. By G. H. BAILEY, D.Sc., Ph.D. Senior Demonstrator of Chemistry, and Lecturer in the Victoria University of Manchester. Macmillan & Co., Ltd., London. The Macmillan Co., New York, 1905. Price 4s. 6d.

SMALL 8vo volume, containing a preface, 241 pages of subject matter, and an alphabetical index. The text contains 47 illustrations, and is sub-divided as follows and for the following purposes:—Chapters I. to IV. contain introductory remarks and instructions of general application; V. to VI., the methods of preparation and analysis of well-defined compounds such as may provide a training in manipulation; Chapters VII. to XIII. are devoted to Volumetric and Gas Analysis; XIV. to XIX., to Methods applicable to the Analysis of Minerals, duly classified; XX., to Processes specially employed in investigating Minerals containing the rarer elements; XXI. to XXIII., to the Technical Analysis of (i) Water and Fuel, (ii) Products of the Alkali Industry, and (iii) Materials containing Organic Matter.

JOURNAL OF THE Society of Chemical Industry.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8s. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie, 56, Rue des Francs-Bourgeois, Paris (3*).

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome, commencing on April 25th, 1906. All communications should be addressed to the General Secretary, Prof. Vittorio Villavecchia, Via Panisperna, 89, Rome.

Members are reminded that the subscription of 25s. for 1906, payable on January 1st, should be sent in good time to the Hon. Treasurer (Mr. Samuel Hall) in order to ensure continuity in the receipt of the Society's Journal.

DECENNIAL INDEX, 1896-1905.

A Collective Index to the first fourteen volumes of the Journal (1882-1895), a volume of 560 pages, was published in 1899; a few copies of this are still left, price 10s. A second volume, embracing the period 1896-1905, is now in preparation, and will be ready for printing in 1906. It will contain both a subject matter and authors' names portion, and will be a volume of about 900 pages, uniform in size with the Journal. As the number of copies to be printed will depend on the number of applications from members, the Treasurer is prepared to receive subscriptions at the rate of 10s. each copy. A form of application for this purpose will shortly be issued.

EXTRAORDINARY GENERAL MEETING.

The attention of members of the Society is drawn to the notice which accompanies this issue of the Journal, of an extraordinary general meeting of the Society to be held at 3.30 p.m. on Tuesday, the 27th March, 1906, at the House of the Society of Arts.

The meeting is convened under Bye-Law 40, in pursuance of a requisition received by the Council, for the purpose of considering and, if approved, adopting a resolution in favour of taking steps to procure the grant of a Royal Charter of Incorporation.

List of Members Elected.

January 23rd, 1906.

- Allan, David, c/o Price's Patent Candle Co., Ltd., Belmont Works, Battersea, S.W., Chemist.
- Ash, Charles S., 661, 3rd Street, San Francisco, Cal., U.S.A., Chemist.
- Bailey, Ralph W., c/o Messrs. Stillwell & Gladding, 55, Fulton Street, New York City, U.S.A., Chemist.
- Bottomley, W., c/o The United Alkali Co., Ltd., Fleetwood Salt Works, Fleetwood, Engineer.
- Bowen, Ralph A., c/o National Aniline & Chemical Company, 36, Purchase Street, Boston, Mass., U.S.A.
- Bradley, R. H., Wellington Foundry, Newark-on-Trent, Engineer.
- Browne-Cave, E. J. C., "Strathallan," Bootle, Liverpool, Works Chemist.
- Buckie, Robert H., c/o The British Uralite Co., Ltd., Higham, near Rochester, Kent, Works Chemist.
- Cabot, Samuel, 141, Milk Street, Boston, Mass., U.S.A., Manufacturing Chemist.
- Carey, William G., 65, Ickburgh Road, Upper Clapton, London, N.E., Chemist.
- Chaplin, Wm. H., 13, Pennywern Road, Earl's Court, S.W., Wine Merchant.

Scammony Root; Presence of Pentoses and Methyl-pentoses in —. P. Requier. J. Pharm. Chim., 1905, 22, 540—542.

In addition to saccharose, previously recorded (this J., 1905, 1246) as a constituent of scammony root, the presence of pentoses and methyl-pentoses is now established.

Saccharine constituents of fresh root.—These, calculated on the dry root, are:—Reducing sugars, as dextrose, 2.70 per cent.; saccharose, 6.80 per cent.; methyl-pentose, 0.95 per cent.; pentose, traces.

Saccharine constituents of dried root.—Reducing sugars as dextrose, 1.11 to 1.81 per cent.; saccharose, 2.08 to 3.30 per cent.; methyl-pentose, 0.226 to 0.253 per cent.; pentose, 0.05 to 0.065 per cent.—J. O. B.

Trade Report.

NEW ZEALAND; EXPORT TRADE OF —.

Bd. of Trade J., Dec. 28, 1905.

In the following table are given the values of exports of certain articles from New Zealand in the years ended Sept. 30, 1904 and 1905:

	Year ended 30th September	
	1904.	1905.
	£	£
Wool	4,331,000	5,542,000
Tallow	371,000	345,000
Butter	1,360,000	1,413,000
Sheep skins	496,000	465,000
Gold	2,052,000	2,035,000

PROF. FRANKLAND, F.R.S., IN THE CHAIR.

A METHOD OF DETERMINING THE TURBIDITY OF WATER.

BY J. F. LIVERSEEGE, F.I.C.

In the practice of water analysis it is often useful to observe the turbidity of samples of water in a glass tube 2 ft. long. For some years I used the following scale:—

"Clear."

"Very slightly turbid—small print legible"

"Slightly turbid"—small print visible, but not legible.

"Turbid"—all print invisible, end of tube visible.

"Very turbid"—end of tube invisible.

This scale had the disadvantage of using words instead of numbers, of having too few steps between "clear" and "very turbid," and of the indefiniteness of "small print."

I thought that greater precision might be obtained by the use of the tintometer, or by observing a vertical column of water, the height of which could be varied according to the turbidity of the sample, but the rapidity with which some waters deposit their sediment made it necessary that the observation tube should be closed and periodically shaken.

As the tube must be closed, it is convenient to vary the size of the type and keep the length of the tube constant. Test type as used by oculists is suitable for the purpose. The type is mounted on a board attached to a cord running over a pulley, and is arranged about 6 in. from the end of the tube, or about 2.5 ft. from the eye. The type is raised or lowered till the set is found which can be easily read. When type for 2.5 ft. normal vision can be read through the 2 ft. of water, the turbidity is expressed as "0"; when type which should be read at 4 ft. can just be read at 2.5 ft. with 2 ft. of water between, the turbidity is expressed as $(4-2.5=) 1.5$; and so on, subtracting 2.5 in each case from the number of feet for normal vision of the particular set of type. Proceeding in this way the approximate numerical value of "very slightly turbid" is 0.5 to 1.5, of "slightly turbid" 2.5 to 4.5, of "turbid" 6 to 38, and of "very turbid" over 38. I describe these numbers as "turbidity expressed in feet of distance to read standard type." The set of test type I use was designed by G. Cowell, and is published by Messrs. Nitsche and Günther, 66, Hatton Garden; the range is from 2 to 40 ft. of normal vision.

When the water is so turbid that 2 ft. of it obscures the type entirely, a tube 1 ft. in length may be used, still reading at 2.5 ft. from the type. I expected that the numbers of the 1 ft. tube would be one-half, or perhaps one-quarter, of those found with the 2 ft. tube, but the proportion is nearer one-tenth. In these circumstances, it is better not to attempt to calculate from one tube to the other, but to give the turbidity numbers and the length of the tube as well.

To make the illumination as constant as possible, I obtained light from a window facing north and take readings in the morning only. During the year I have used this method regularly and have found it advantageous in comparing a series of waters from month to month.

DISCUSSION.

Dr. T. S. PRICE asked if the amount of turbidity would depend on some power of the length of the tube?

The CHAIRMAN said that the determination of the different degrees of turbidity in water was a matter of very great importance, for the reason that the filtration of water, which was probably carried on with the object of removing bacteria, could not be controlled by bacteriological examination without some considerable delay. Two days at least were required before the operation of the filters could be satisfactorily checked. Any method of determining the turbidity rapidly became, therefore, of immense importance in engineering. It was impossible that any bacteriological method could throw such rapid light on the subject as the determination of the turbidity, or otherwise, of water.

Mr. LIVERSEEGE, in reply, said he knew of no law which had been formulated to give the relation between the amount of light passing and the length of the turbid liquid. The proportion between 1 ft. and 2 ft. being about one to ten suggested the amount of light that might vary inversely as the cube of the length. He was not sure that the method would be exact enough for testing bacteriological filtration. Probably the difference between 0 and 0.5 would be a serious difference, bacteriologically. The method would be more useful for unfiltered waters.

THE INFLUENCE OF SMALL QUANTITIES OF ELEMENTS IN COPPER UPON ITS REACTIONS WITH NITRIC ACID.

BY J. H. STANSBIE, B.Sc., F.I.C.

The character of the reactions which take place when pure metals are dissolved in nitric acid has been the subject of many investigations, and the general effects of diluting the acid and of varying the temperature at which the dissolution takes place, are well known. Also, the effects of the presence of nitrous acid in the nitric acid solution, and of nitrates formed during the dissolution of the metals in it have received much attention. Aesworth, Armstrong, Gladstone and Divers are among those who have done much work in this direction, but very little seems to have been done in the direct investigation of the effects of impurities in the metals themselves upon their general reactions with the acid, and it is to this end that the work described in this paper is directed.

Given a sample of the pure metal and a solution of nitric acid it may be stated that the volume and composition of the gas liberated by the dissolution of a given weight of the metal in a given volume of the acid will depend upon the dilution of the acid and the temperature at which the reaction takes place. If, however, any one of these conditions is allowed to vary, a variation in the result may be looked for. The work now to be described has for its object the detection and measurement of variations in the volume and composition of the evolved gas caused by the introduction of small quantities of elements into pure copper.

FIG. 1.

The apparatus used is of simple form and readily controlled. It is shown in Fig. 1. The reaction is carried out in a small beaker A fitted with a rubber bung through which pass an angle tube for the escape of the gas, a delivery tube with a narrow bore for the addition of the acid, and a thermometer to determine the temperature of the reaction. The bottom of the bung is cut away at a small angle near the gas tube, and the under surface coated with a thin film of paraffin wax. The acid delivery tube is connected with the burette B, from which the measured quantity of the acid solution is run into the beaker. The lower part of the burette is surrounded by a water jacket C, for raising the temperature of the acid, and the lower part of the beaker is immersed in a water bath D. A graduated cylinder, fitted with an angle tube and stopcock, and standing in an inverted bell jar F, is used for collecting and measuring the evolved gas. A second bell jar G is connected with the first jar by a flexible tube, and is so arranged that it can be raised or lowered to regulate the level of the water in the first jar to the requirements of the experiment in hand.

The oxygen apparatus consists of an ordinary drying cylinder, having a tap funnel connected to the tubulure at the bottom of the cylinder by a flexible tube. The cylinder is graduated and is fitted with a rubber bung and delivery tube.

An experiment is carried out as follows:—The metal is reduced to filings, which are sifted through brass gauze with 64 meshes to the linear inch, and the sifted portion is carefully magnetized to remove particles of iron derived from the file. One gram. of the filings is transferred to the dry beaker. The rubber bung, to which the burette is attached, is held in position by a retort clip, the acid run into the burette and levelled. The beaker is then pressed on to the bung, the measuring cylinder attached, and a water lute run between the rim of the beaker and the side of the bung to ensure the apparatus being gas tight when in position. Hot water is poured into the water-jacket surrounding the portion of the burette containing the acid. The hot water bath in which the beaker is to be partly immersed is now prepared and brought into position, and one minute allowed for the beaker to come to the temperature of the bath. The acid is then allowed to run in slowly, and the temperature noted. When the action is finished water is poured into the burette, and allowed to run into the beaker. In this way the whole of the gas is transferred to the measuring cylinder. The water is levelled and the volume of the gas read off. The level of the water in the bell-jar is then raised, its temperature taken, and a measured volume of oxygen added to the gas in the cylinder. The cylinder is shaken to remove the last traces of nitric peroxide, allowed to stand for a minute, and the volume of gas again read off. The height of the barometer is then taken, and the experiment is finished.

The water over which the gas is collected and the oxygen apparatus are allowed to come to the same temperature before use.

The following example shows the method of working:—Volume of air in apparatus before the addition of acid = 45 c.c.; volume of gas in cylinder = 215 c.c.; volume of oxygen added = 125 c.c.; volume of residual gas = 73 c.c.; temperature = 20.9°C.; pressure = 756 mm.

From the data thus obtained it is easy to find the volume of nitric oxide originally present in the collected gas, and this, together with the volume of nitric oxide already removed by the oxygen of the air present in the apparatus at the beginning of the experiment, gives the total volume of nitric oxide liberated from the acid solution. The volume of the gases other than nitric oxide is also readily determined.

In the experiment in which the above measurements were made the volume of nitric oxide, corrected to the dry gas at N.T.P., obtained by the dissolution of 1 gram. of pure copper in 15 c.c. of nitric acid (sp. gr., 1.2) at 65°C. was 176 c.c., and the volume of the other gases 1 c.c.

The standard copper used in the experiments was obtained by fusing the electro-deposited metal under charcoal in a carbon crucible, and well agitating the molten metal in contact with the charcoal. The metal was then allowed to solidify under charcoal so as to prevent

absorption of oxygen during solidification, and gave on electrolytic assay Cu = 100.04 per cent.

Variations in Temperature.—A number of experiments were made to determine the general effect of varying the temperature at which the reaction takes place. One gram. of copper was dissolved in 15 c.c. of nitric acid (sp. gr. 1.2). The experiment was carried out exactly as described above, and the temperature was regulated by the water-jacket and water-bath. The time required for complete dissolution was noted. The results are given in the following table, and are also plotted on the curves, Fig. 2:—

Time in min.	Temperature in °C.	Volume of Nitric Oxide.	Total Volume of Gas Liberated.
		c.c.	c.c.
58	25	137.5	142.0
30	35	139.5	145.5
16	45	153.0	157.0
6	55	163.0	167.0
5	65	176.0	179.0
5	75	182.0	185.0
4	85	185.0	186.0
3	95	192.0	193.5

FIG. 2.

Reference to the curves makes it clear that increase in the temperature at which the reaction takes place causes a considerable increase in the volume of nitric oxide liberated, and a slight decrease in the volume of gas other than nitric oxide.

Dilution of the Acid.—Nitric acid of sp. gr. 1.2 contains 5.8 grms. of nitric acid in 15 c.c. of the solution. In determining the effect of dilution on the volume and composition of the evolved gas, it was arranged that the volume of acid solution used for each experiment should contain 5.8 grms. of nitric acid. The other conditions were kept as constant as possible and the temperatures actually observed varied little from 70°C. One gram. of standard copper was used for each experiment, and the results are embodied in the following table:—

Volume of Acid Solution.	Volume of Nitric Oxide.	Total Volume of Gas.
c.c.	c.c.	c.c.
20.0	158.5	159.5
15.0	177.5	178.5
12.5	167.5	170.0
8.5	180.0	183.0
6.5	74.0	80.0

It was evident from the last two experiments that the quantity of nitric peroxide in the apparatus largely exceeded that which would be formed by the union of nitric oxide with the oxygen of the air present in the beaker at the beginning of the reaction. Therefore, nitric peroxide is clearly a product of the reaction when the acid solution exceeds a certain strength. From

several considerations it was decided to use nitric acid of 1.2 sp. gr. for the general experiments, and to keep the temperature of the reaction about 65° C.

Varieties of Commercial Copper.—The following results show the necessity of using pure copper for the standard experiments:—

Varieties of Copper.	Volume of Nitric Oxide.	Total Volume of Gas.
	c.c.	c.c.
Copper for electrical work	177.0	179.5
Dry copper	158.5	160.0
Rod copper (rolled)	152.0	162.5
Sheet copper (hard rolled)	148.5	162.0

The ordinary impurities in commercial copper thus affect the volume and composition of the gas liberated by the dissolution of the metal in nitric acid. The sample of dry copper given in the above table was prepared by melting pure copper in contact with air; so that oxygen, which is generally present in the commercial metal, has the same general effect as other impurities.

Pure Copper.—In a number of experiments with the pure standard copper and nitric acid (1.2) at a temperature of 65° C., 1 gram of the metal gave 175 to 177 c.c. of nitric oxide, and it was decided to take 176 c.c. as the standard volume for the nitric oxide liberated under the above conditions, and 177 for the total volume, so that the liberated gas is practically all nitric oxide. From the equation commonly accepted, it is found that 1 gm. of pure copper should liberate 234 c.c. of nitric oxide. Therefore, there is a deficiency of 25 per cent. in the volume of gas actually collected. As nitric oxide is only slightly soluble in water, and as the gas is delivered on to the surface of the water in the collecting cylinder, and is only in contact with it for about 10 minutes, this source of error may be neglected. But nitric oxide is somewhat freely soluble in nitric acid and nitrate solution, and some experiments were made to determine how far this solubility would account for the deficiency noticed above, assuming the equation to be correct.

The absorption apparatus consists of a short glass cylinder of 25 c.c. capacity, fitted with a rubber bung and two angle tubes. The longer of the two tubes has a narrow bore, and is expanded at one end into a flat disc which, when the tube is in position, presses on to a pad of glass wool at the bottom of the cylinder. This arrangement breaks up the bubbles as they escape from the tube, and brings the gas well into contact with the absorbing liquid in the cylinder. Also, no difficulty is experienced in displacing the whole of the gas in the apparatus at the end of the experiment.

The only difference in the arrangement of the apparatus for these experiments, and that already described, is in the introduction of the absorption tube between the beaker and the collecting cylinder. A second water-bath is used to bring the absorption tube to the required temperature.

A number of experiments were carried out as follows:—One gm. of standard copper was dissolved in 15 c.c. of nitric acid (1.2) at 65° C., and the gas passed through the absorption tube into the collecting cylinder. The gas remaining in the apparatus was then driven into the cylinder and the nitric oxide estimated.

Fifteen c.c. of the absorbing solution at 65° C. were used for each experiment.

Absorbing Solution.	Volume of Gas absorbed.
	c.c.
Nitric acid (1.2) alone	59.0
" " with 1 gm. of copper dissolved in it and the solution gently boiled for 5 mins.	35.0
" " with 1 gm. of copper dissolved in it and a current of air blown through the solution	30.5
" " with 1 gm. of copper dissolved in it	2.5
Neutral solution of copper nitrate	12.0

These experiments simply confirm the well-known facts that nitric acid and copper nitrate in solution absorb nitric oxide, and further that this absorption accounts, largely at any rate, for the difference between the volume of the gas actually collected, and that indicated by the usual equation. For it is worthy of notice that the volume of nitric oxide absorbed by nitric acid at 65° C., added to the volume liberated by the copper at 65° C., gives roughly the volume calculated from the equation.

Influence of Arsenic, Antimony, and Bismuth.—The part of the work now to be described is a systematic examination of the effects of arsenic, antimony, and bismuth when introduced separately into copper, upon the reaction of the latter metal with nitric acid. From what has been said already in connection with the effects of the impurities present in commercial copper, it is clear that considerable care must be exercised in the preparation of the alloys so as to ensure that only the two metals under consideration shall be present in them. In the preparation of these alloys, it was found convenient to prepare a rich alloy of copper and the other metal, and to use weighed portions of this alloy to introduce the second metal into fresh portions of pure copper. The preparation of an alloy was carried out as follows:—

The weighed quantity of copper was melted under charcoal in a carbon crucible, and well agitated in contact with the charcoal; the weighed quantity of rich alloy was then dropped in and the metal well agitated to ensure perfect mixture. The pot was withdrawn from the fire and allowed to cool with the lid on, the surface of the alloy being further protected from the atmosphere by the layer of charcoal. In this way, complications due to the absorption of oxygen by the solidifying alloy were avoided. The button of alloy was weighed when cold, and its weight compared with the weight of metal used in its preparation. The buttons usually prepared weighed 200 grains, and the loss during preparation was generally less than 0.2 grain. The alloys containing arsenic and antimony showed no signs of liquation, and their composition was taken as prepared; but those containing bismuth showed signs of liquation even below 1 per cent. of bismuth. Above 1 per cent. the liquation was very marked, small globules being extruded through the surface of the buttons. A number of these globules were detached from the buttons and analysed. The analysis gave 99.7 per cent. of bismuth, and the ammoniacal solution, from which the bismuth was precipitated, had a faint blue colour due to the presence of a trace of copper. But, since it would be practically impossible to detach the globules from the buttons without bringing away a little of the alloy, this trace of copper must be regarded as adventitious. Therefore, a solidifying alloy of copper and bismuth rejects pure bismuth, and this is so even when the content of bismuth exceeds 50 per cent. It was, therefore, necessary to analyse the series of copper-bismuth alloys prepared for the experiments to be described later, and, as the amount of liquation could not be controlled, the composition of the series is not as uniform as that of the antimony and arsenic series.

The arsenic antimony, and bismuth used in the preparation of the alloys were specimens of the ordinary pure metals, and as not more than 3 per cent. was put into an alloy, only the merest traces of impurities would be thus introduced.

In order to make the comparison as complete as possible, 1 gm. of each of these metals was dissolved in 15 c.c. of nitric acid (1.2), the gas collected and determined. The arsenic and bismuth dissolved readily at 65° C., but the antimony was oxidised slowly even at 94° C. The following tables gives the volumes of the dry gas at N.T.P.:—

	Nitric Oxide.	Total Gas.	Temperature.
	c.c.	c.c.	°C.
Arsenic	327.0	330.0	67
Antimony	168.0	169.5	94
Bismuth	79.5	81.0	67

Reference to the table renders it evident that nitric oxide is the principal gaseous product of the dissolution of arsenic and bismuth in the 1.2 acid, for 99 and 98 per

The apparatus used is of simple form and readily controlled. It is shown in Fig. 1. The reaction is carried out in a small beaker A fitted with a rubber bung through which pass an angle tube for the escape of the gas, a delivery tube with a narrow bore for the addition of the acid, and a thermometer to determine the temperature of the reaction. The bottom of the bung is cut away at a small angle near the gas tube, and the under surface coated with a thin film of paraffin wax. The acid delivery tube is connected with the burette B, from which the measured quantity of the acid solution is run into the beaker. The lower part of the burette is surrounded by a water jacket C, for raising the temperature of the acid, and the lower part of the beaker is immersed in a water bath D. A graduated cylinder, fitted with an angle tube and stopcock, and standing in an inverted bell jar F, is used for collecting and measuring the evolved gas. A second bell jar G is connected with the first jar by a flexible tube, and is so arranged that it can be raised or lowered to regulate the level of the water in the first jar to the requirements of the experiment in hand.

The oxygen apparatus consists of an ordinary drying cylinder, having a tap funnel connected to the tubulure at the bottom of the cylinder by a flexible tube. The cylinder is graduated and is fitted with a rubber bung and delivery tube.

An experiment is carried out as follows:—The metal is reduced to filings, which are sifted through brass gauze with 64 meshes to the linear inch, and the sifted portion is carefully magnetized to remove particles of iron derived from the file. One gram. of the filings is transferred to the dry beaker. The rubber bung, to which the burette is attached, is held in position by a retort clip, the acid run into the burette and levelled. The beaker is then pressed on to the bung, the measuring cylinder attached, and a water lute run between the rim of the beaker and the side of the bung to ensure the apparatus being gas tight when in position. Hot water is poured into the water-jacket surrounding the portion of the burette containing the acid. The hot water bath in which the beaker is to be partly immersed is now prepared and brought into position, and one minute allowed for the beaker to come to the temperature of the bath. The acid is then allowed to run in slowly, and the temperature noted. When the action is finished water is poured into the burette, and allowed to run into the beaker. In this way the whole of the gas is transferred to the measuring cylinder. The water is levelled and the volume of the gas read off. The level of the water in the bell-jar is then raised, its temperature taken, and a measured volume of oxygen added to the gas in the cylinder. The cylinder is shaken to remove the last traces of nitric peroxide, allowed to stand for a minute, and the volume of gas again read off. The height of the barometer is then taken, and the experiment is finished.

The water over which the gas is collected and the oxygen apparatus are allowed to come to the same temperature before use.

The following example shows the method of working:—Volume of air in apparatus before the addition of acid = 45 c.c.; volume of gas in cylinder = 215 c.c.; volume of oxygen added = 125 c.c.; volume of residual gas = 73 c.c.; temperature = 20.9°C.; pressure = 756 mm.

From the data thus obtained it is easy to find the volume of nitric oxide originally present in the collected gas, and this, together with the volume of nitric oxide already removed by the oxygen of the air present in the apparatus at the beginning of the experiment, gives the total volume of nitric oxide liberated from the acid solution. The volume of the gases other than nitric oxide is also readily determined.

In the experiment in which the above measurements were made the volume of nitric oxide, corrected to the dry gas at N.T.P., obtained by the dissolution of 1 gram. of pure copper in 15 c.c. of nitric acid (sp. gr., 1.2) at 65° C. was 176 c.c., and the volume of the other gases 1 c.c.

The standard copper used in the experiments was obtained by fusing the electro-deposited metal under charcoal in a carbon crucible, and well agitating the molten metal in contact with the charcoal. The metal was then allowed to solidify under charcoal so as to prevent

absorption of oxygen during solidification, and gave on electrolytic assay Cu = 100.04 per cent.

Variations in Temperature.—A number of experiments were made to determine the general effect of varying the temperature at which the reaction takes place. One gram. of copper was dissolved in 15 c.c. of nitric acid (sp. gr. 1.2). The experiment was carried out exactly as described above, and the temperature was regulated by the water-jacket and water-bath. The time required for complete dissolution was noted. The results are given in the following table, and are also plotted on the curves, Fig. 2:—

Time in min.	Temperature in °C.	Volume of Nitric Oxide.	Total Volume of Gas Liberated.
		c.c.	c.c.
58	25	137.5	142.0
30	35	139.5	145.5
16	45	153.0	157.0
6	55	163.0	167.0
5	65	176.0	179.0
5	75	182.0	185.0
4	85	185.0	186.0
3	95	192.0	193.5

FIG. 2.

Reference to the curves makes it clear that increase in the temperature at which the reaction takes place causes a considerable increase in the volume of nitric oxide liberated, and a slight decrease in the volume of gas other than nitric oxide.

Dilution of the Acid.—Nitric acid of sp. gr. 1.2 contains 5.8 grms. of nitric acid in 15 c.c. of the solution. In determining the effect of dilution on the volume and composition of the evolved gas, it was arranged that the volume of acid solution used for each experiment should contain 5.8 grms. of nitric acid. The other conditions were kept as constant as possible and the temperatures actually observed varied little from 70° C. One gram. of standard copper was used for each experiment, and the results are embodied in the following table:—

Volume of Acid Solution.	Volume of Nitric Oxide.	Total Volume of Gas.
c.c.	c.c.	c.c.
20.0	158.5	159.5
15.0	177.5	178.5
12.5	167.5	170.0
8.5	180.0	183.0
6.5	74.0	80.0

It was evident from the last two experiments that the quantity of nitric peroxide in the apparatus largely exceeded that which would be formed by the union of nitric oxide with the oxygen of the air present in the beaker at the beginning of the reaction. Therefore, nitric peroxide is clearly a product of the reaction when the acid solution exceeds a certain strength. From

Similar series of experiments were made with mixtures of copper and arsenic, copper and antimony, and copper and bismuth, to determine the effect of simply mixing two metals as compared with alloying them. The copper and bismuth were used in the form of sifted filings; the arsenic and antimony were powdered in an agate mortar, and the powder sifted. In preparing a given mixture, the required quantity of the other metal was weighed on a watch glass and then made up to 1 grm. with copper. The mixture was treated in exactly the same manner as the corresponding alloy. The results are tabulated below, and are also plotted on the corresponding curve diagrams:—

Mixtures of Copper and Arsenic.

Mixture.		1.	2.	3.	4.	5.	6.	7.	8.	9.	10.
Arsenic per cent.	0-00	0-05	0-10	0-25	0-50	0-75	1-00	1-50	2-00	2-50	3-00
Vol. of nitric oxide	176-0	174-5	174-0	175-0	175-0	175-0	178-0	174-0	174-0	175-0	174-0
Total vol.	177-0	179-0	179-0	177-5	175-5	177-5	176-5	178-0	177-5	179-0	178-0

Mixtures of Copper and Antimony.

Mixture.		1.	2.	3.	4.	5.	6.	7.	8.	9.	10.
Antimony per cent.	0-00	0-05	0-10	0-25	0-50	0-75	1-00	1-50	2-00	2-50	3-00
Vol. of nitric oxide	176-0	174-5	174-0	175-0	175-0	175-0	178-0	174-0	174-0	175-0	174-0
Total vol.	177-0	177-0	170-5	177-5	177-5	178-0	178-5	174-5	177-0	177-5	176-0

NOTE.—Up to 1 per cent. the antimony dissolved completely, beyond that the solution became milky, and a slight dark sediment showed that the antimony was not completely oxidised under the conditions of the experiment.

Mixtures of Copper and Bismuth.

Mixture.		1.	2.	3.	4.	5.	6.
Bismuth per cent.	0-00	0-05	0-25	0-75	1-50	2-00	3-0
Vol. of nitric oxide	176-0	173-5	174-0	174-0	173-5	173-0	171-0
Total vol.	177-0	170-5	177-0	175-0	175-5	175-0	174-0

It has been shown by the foregoing experiments that the presence of impurities in copper, even in very small proportions, modifies the reaction of the metal with nitric acid, and that this effect is altogether out of proportion to the quantity of impurity present. When oxygen is the impurity, the falling off in the volume of gas liberated may be due to part of the metal being already oxidised at the commencement of the acid attack. But the explanation of the action of arsenic and antimony must be looked for in quite another direction. In a pure copper-arsenic alloy, containing an excess of copper the arsenic is present as arsenide, and it is the relation of the arsenide to the excess of copper that confers upon the alloy its characteristic properties. When the alloy is in the molten state it is without doubt a solution; but during solidification this simple composition may be modified, and a number of changes may take place, such as the crystallisation of pure copper, the formation of eutectics, and the segregation of the arsenide itself. But as all or any of these changes would result in the more or less complete separation of the main bulk of the copper from the arsenide, it is difficult to see how the presence of arsenic in such a mixture could seriously affect the action of nitric acid upon it.

It would appear that a much more intimate relation of the arsenic with the whole mass of the copper is required, and the condition of most intimate relation of the arsenic with the whole of the copper would be furnished by a perfect solid solution. Thus, the minimum action would be given by the alloy containing the percentage of the added metal which gave the most perfect solid solution. If this view is correct the point is reached for copper-arsenic when the arsenic equals 0-25 per cent., and for copper-antimony when the antimony equals 0-5 per cent. Also, the behaviour of the copper-bismuth alloys seems to indicate the absence of solid solutions from their compositions.

The investigation furnishes another example of the marked influence of small quantities of elements, both metals and non-metals, upon the properties of metals, about which there is still much to be said. A more extended research is in progress, and may throw further light on the subject.

It may be suggested that, in carrying out this research, it would have been more complete if the composition of the residual gas had also been determined; but as the chief aim of the present work was rather to prove a differential action than to give complete analytical details, this was not attempted. Nitric oxide is the principal gas liberated by the metals present in the alloys under

consideration, and is readily estimated with sufficient accuracy for the purpose. It is here regarded as an indicator of variations in the chemical change due to variations in the composition of the metal producing it.

Refinements in the methods employed have been left for future work.

DISCUSSION.

Dr. T. S. PRICE said that many investigations had already been carried out as to the action of nitric acid on different metals, and the action varied very much with the strength of nitric acid used. The presence of nitrous acid had been found by Veley and others to have great influence. Did Mr. Stansbie investigate to see if there were other substances present which might affect the results? The presence of nitrous acid and other substances in the nitric acid was so very important that he should have thought it would have been taken into account at the very beginning of the investigation. The subject was a very complicated one. He had had occasion recently to look up accounts of the action of nitric acid on metals, and they seemed to be very contradictory.

The CHAIRMAN did not quite agree with Dr. Price regarding the influence of nitrous acid, because of the great consistency of the results which Mr. Stansbie appeared to have obtained. If it were due to accidental impurities of that kind such uniform results would not be expected. The two tables seemed to him to contain the pith of the matter, and the results were extremely remarkable—the influence of the limited proportion of arsenic and the nature of the gas evolved. With regard to the other gases, he supposed they were largely nitrogen and nitrous oxide. The discrepancies between the amounts obtained, viz., 137 c.c. at 25° C., and 192 c.c. at 95° he supposed was due to the insolubility of nitric oxide in hot nitric acid and copper nitrate solution.

same way as in what is termed martensite. With 0.8 per cent. of manganese, the needle-shaped crystals are smaller and the segregated portions more extended and more continuous, tending to enclose spaces composed of the needle-shaped crystals and the dark ground work. With 1.5 per cent. the needle-shaped crystals are very small and very fine. Evidently they are of the same composition as the segregated portions, which now form continuous boundaries to the dark groundwork, in some parts narrow and in others very wide and massive.

With further increase of manganese, the segregated portions get larger and larger, the needle-shaped crystals almost disappear, and the whole field is composed of two portions—the double carbide of iron and manganese forming the hard white prominent boundary masses and the dark ground, containing very small but irregular needle-shaped crystals, giving it the appearance of a eutectic nature.

Fig. 7 illustrates this structure. The sample contains 2.3 per cent. of manganese. Manganese has a more powerful influence on the condition of carbon than silicon, for with equal parts of silicon and manganese there is much more combined carbon than graphite, and a total absence of large flakes of graphite. This is probably due to the fact that manganese readily unites with carbon, while silicon does not, and that a double carbide of iron and manganese is produced in cast iron in the absence of sulphur and silicon. When silicon is present, the manganese can unite with it, and thus neutralise any power the silicon may possess of causing the separation of graphite.

To further test the effect of manganese on cast iron, a cast iron, practically free from silicon, was taken, and 1.5 per cent. of manganese added. This alloy, when thoroughly melted, was kept some time in the molten state, then transferred, in a covered crucible, to a muffle, as before described and kept at a temperature of 1100° C. for some hours and allowed slowly to cool. Notwithstanding the slow cooling the metal was white, hard, and had the same structure as the preceding ones.

Effect of Phosphorus.—Our present knowledge of the effect of phosphorus on iron is largely due to the researches of Mr. J. E. Stead, whose work on the subject is known to all iron metallurgists. When the action of phosphorus on iron is considered his results may be taken as conclusive and almost exhaustive. He pertinently remarks ("Jour. Iron and Steel Inst." No. 11, 1900) "the study of binary alloys is comparatively easy compared with the research relating to compounds of iron with carbon and phosphorus."

In such compounds the carbide and phosphide often exist side by side, and more etching is often insufficient to distinguish one from the other. The method of heat tinting has been found by Osmond and Stead to be most effective in indicating the phosphide and carbide areas, because the carbide takes the deeper line on heating to a given temperature. Both the carbide and the phosphide are intensely hard, but Stead considers the carbide the harder of the two. On heating cast iron containing phosphorus at 900° C. and cooling moderately rapidly, the phosphide passes into solid solution, and is, on cooling, distributed between the newly-formed pearlite grains, and, therefore, behaves in a similar manner to that of steel free from phosphorus. As the carbon increases the phosphorus is thrown out of solution and exists as a free phosphide.

In order to ascertain the effects of varying proportions of phosphorus on cast iron, practically pure iron was melted with phosphorus, from 0.25 to 2.0 per cent. First, a rich phosphoric cast iron was made and analysed to get the percentage of phosphorus. From this rich alloy, when added to the iron and carbon were obtained the above-mentioned alloys.

The alloys were prepared in the same way as the previously mentioned alloys, kept at a high temperature for a long time, and slowly cooled. The alloy with 0.25 per cent. of phosphorus was found to consist of two chief parts—a massive, hard, white portion of cementite of very irregular shape and a mixture of a fine structure forming the eutectic. In this eutectic a number of white needle-shaped crystals crossed the ground in different directions, and are probably cementite.

With 0.5 to 1.0 per cent. of phosphorus, the eutectic matrix is divided into elongated grains, the boundaries of which are composed of the phosphide eutectic in some parts and massive cementite in others. The cementite also segregated in large structureless masses in other parts of the section. The ground mass was of a eutectic nature, but the phosphide was evidently largely concentrated in the boundaries of the grains. This structure is shown in Fig. 8, which contains 1.0 per cent. of phosphorus.

With higher percentages, as in Fig. 9, which contains 2 per cent. of phosphorus, the ground mass is entirely pearlitic and probably contains some phosphorus, but the greater part is in the portions of the boundaries parallel with the cementite masses, which are white and structureless. This would not be the case if they contained any notable quantity of phosphorus. They may contain some phosphorus in solid solution, but the quantity is probably very small.

The question may now be asked: Does phosphorus in any way influence the condition of carbon in iron? This is a difficult thing to prove absolutely. In the first place, the fractured surface of pure cast iron (iron and carbon), when allowed to cool slowly in the same way and at the same rate as phosphoric cast iron, was found to be of a grey colour, while all those containing phosphorus were white. This would seem to indicate that phosphorus induces combined carbon; but the phosphide of iron is also white, and the light colour may be due to the phosphide. On the other hand, the polished and etched sections show very much greater portions of massive cementite than in the case of pure cast iron, the structure of which was finer and the crystal grains smaller. This is, in accordance with Mr. Stead's observation, that phosphorus promotes the formation of large crystals.

An interesting sample of the combined effect of phosphorus and silicon was brought to me some time ago by Mr. Buchanan, the analysis of which is as follows.—Combined carbon, 0.2; graphite, 2.0; phosphorus, 2.1; manganese, 0.3; silicon, 1.95 per cent. The structure is shown in Fig. 10. In this case the phosphorus is exceptionally high, and is in excess of the silicon. The fractured surface was grey, and the metal close grained, but, on trying to drill it, it was found to be too hard for the drill to cut it. The micro-section contains large plates of graphite like ordinary grey iron. The phosphorus eutectic is abundantly evident in all parts, and there is also the usual eutectic matrix.

Now, in this case, the phosphorus did not make the iron white, and the silicon did not make portions of it grey. I consider that, in this case, the silicon and phosphorus tendencies were inoperative, and that the natural tendency to form graphite by the slow rate of cooling predominated. The iron is grey due to the graphite, and a portion is white due to the combined carbon and combined phosphorus.

The presence of phosphorus in cast iron lowers the percentage of total carbon, and this effect increases proportionately with the increase of phosphorus. The amount of carbon in cast iron with 2 per cent. of phosphorus is probably not more than 2 per cent., so that as regards the carbon, the metal is more like steel than cast iron. Now the more steel-like the metal is the less is the tendency to form graphite, and the greater the tendency to form combined carbon. In this respect the influence of phosphorus acts indirectly, if not directly, towards the formation of combined carbon.

Effect of Sulphur.—Sulphur, even when present in small quantities, exerts a considerable influence on cast iron. It is generally agreed that sulphur exists in iron as a sulphide of iron, and when manganese is present, as sulphide of manganese. The former is readily fusible and decomposed at high temperatures, the consequence being that when the metal is slowly cooled from a high temperature a large proportion of the sulphur escapes as a gaseous compound, giving the metal a very spongy texture. With the presence of manganese the sulphur combines with that element in preference to the iron, and as this manganese sulphide has a high melting point and a high dissociation point, the sulphur is not liberated in the gaseous form, so that blowholes and red shortness are avoided to a great extent.

Endeavours were made in vain to get a good clear section by slowly cooling cast iron, into which had been introduced from 0.25 to 2.0 per cent. of sulphur, in consequence of the volatility of the sulphur compound. On quickly cooling a sulphury iron a better surface may be obtained, but blowholes are even then abundant. The structure is somewhat similar in each case, but the quickly cooled sample is finer in grain and the constituents more evenly arranged.

Fig. 11 is a section of pure cast iron to which 1 per cent. of sulphur has been added, and cooled very slowly. The fractured surface was white. The polished and etched surface had the appearance of high carbon steel, with grains of perlite and boundaries of cementite, and across the grains ran needle-shaped crystals of cementite in various directions. There were no flakes of graphite. The sulphide of iron appears to have been located in the boundaries, as the blowholes follow the contour of these boundaries. Some sulphide still remained and had a bluish-grey colour after etching in dilute nitric acid. Also, on etching, the well-known colour of sulphuretted hydrogen may be perceived. It may be incidentally remarked that very dilute nitric acid also causes the liberation of sulphuretted hydrogen.

Sulphur appears to act in the same way as manganese in causing the carbon to assume the combined form, or, rather, to prevent the carbon in solution from separating as graphite.

DISCUSSION

Prof. THOS. TURNER said that the question of the separation of graphite from cast iron was one which was of very great interest both from the practical and theoretical point of view. It was only within the last few years that anything really accurate or definite had been learned on the subject, and, as Mr. Hirns had pointed out, the first step in that knowledge was due to Ledebur's recognition of temper carbon or temper graphite as being distinct from the ordinary form of graphite. Following that came microscopical observations, and it was soon recognised that graphite was of different sizes and different kinds. A good deal of work in connection with that branch of the subject had been done in the laboratory of the University of Birmingham by Mr. O. F. Hudson. He (Prof. Turner) had followed up that line of argument also by separating the pure graphite from a considerable weight of iron and sitting the graphite, as obtained from the various grades of iron, through a series of sieves, and it was found that the size of the graphite determines the grade of the iron. It was not the quantity of the graphite, but the actual size of the separate flakes, that determined the "number" of the iron. They had also recently had experiments in progress bearing on the rate and the temperature at which the graphite separated. These experiments had to do with the volume alterations of cast iron, and with the determination of the temperature at which these volume changes occurred. There were two chief expansions in the iron as it cooled, and also two arrests in the temperature during cooling. One of these corresponded to the separation of the ordinary flake graphite and the other to the formation of temper graphite. The size of the graphite varied according to the temperature, at which it was produced. The higher the temperature the larger were the flakes of graphite. Kish, which separated from fluid cast iron, was the largest form of graphite. As the metal solidified when the large graphite separated out, the operation was not complete in a single moment, but it was a process requiring time. In the same way, when the temper graphite was produced, some time was required, and he was of opinion that Mr. Hirns was quite correct when he stated that the amount of graphite, and the kind of graphite, were largely a function of time and temperature. At the same time the importance of other conditions must be recognised, particularly that of the constituents which were present. It was extremely difficult to say how much silicon was necessary in order to produce graphitic carbon, and it would vary very much with the proportion of other elements. Grey cast iron could be produced on a large scale with less than half per cent. of silicon. That, of course, was quite exceptional, but in the ordinary way and under ordinary

circumstances some silicon was essential to the production of graphitic carbon. The purer the iron the less silicon was required, but that some silicon was required seemed to be proved by constant experience.

Mr. BUCHANAN said he had no doubt whatever that, with phosphorus, hardening was attained directly and not necessarily from the combined carbon, and he had yet to see a phosphoric iron with high sulphur. He had never seen a cinder pig with a high sulphur content so long as it had a high percentage of phosphorus. It was a singular fact that manganese and sulphur, which separately hardened iron by causing combined carbon, had the effect of softening it when together in the same iron, and so lowering the combined carbon. A case was brought to his notice recently in which large quantities of cast iron had been spoiled in the melting; it contained a high percentage of sulphur and was perfectly white. It was melted with scrap and a pig containing somewhere over 2 per cent. of manganese, and a grey pig was obtained. As regards manganese sulphide, he had seen a number of micro-sections, the manganese sulphide in the cementite was of rectangular form. In one case the manganese sulphide was to be seen in the pearlite as well as in the cementite. The sulphur present was 0.25 per cent., probably due to the large quantity of manganese sulphide present; some of it found its way into the pearlite. If pearlite was a eutectic, how could phosphorus eutectic be found in the cementite? He took it that the phosphorus eutectic was in a fluid condition and that the cementite was set. How was it that the phosphorus eutectic had been driven into the cementite areas? As regards the effect of cooling on the separation of graphite, the time element was most important. In the micro-section of a piece of cast iron which has been annealed, it could be seen that the annealing carbon had come up to the surface of what had been cementite. That separation of annealing carbon could hardly be due to the silicon present unless the silicon had an expellent effect on the carbon after the metal was in a solidified form. His own ideas as regards the separation of graphite through the influence of silicon was that it took place when the iron was in a pasty condition, very little below its setting point. But with the ordinary annealing, where the iron had retained its solidified form, it externally changed when the annealing carbon separated from the cementite. It must be due to the temperature, as it seemed improbable that it could be due to the influence of the silicon when the iron was in the solid form. The temperature was not high enough to allow the silicon to act in the way it was usually supposed to do.

Mr. W. ROSENBAUM referred to the process of heat tinting to which Mr. Hirns had alluded in connection with the detection of the presence and distribution of phosphorus. This process was a most useful one, and was consequently much recommended in the literature of the subject. For that reason the speaker wished to sound a note of warning as to certain very serious obstacles which had to be overcome in connection with the method. When a polished section of metal was exposed to the oxidising action of the atmosphere at a high temperature, only the actual surface of the metal was exposed; and this actual surface very often did not represent the real structure of the metal, because the very act of polishing tended to spread the softer constituents over the harder, and in all cases produced a definite layer of altered material. When such a surface was etched, the altered layer was removed, and if the etching was to show the true structure of the metal it must be carried deep enough to remove the altered layer entirely. Merely exposing the surface to oxidation did not remove the altered layer, and it had consequently been found necessary to etch the surface first and heat-tint afterwards. Another difficulty in heat-tinting arose from the difficulty of obtaining the surfaces in a perfectly clean state; whatever solutions were used for washing or etching, some residue was always liable to remain on the surface and to affect the rate of oxidation. Two very serious difficulties had thus to be overcome before heat-tinting could yield satisfactory results.

Dr. A. FINDLAY said he had listened to the paper from the theoretical side with great pleasure, more especially on account of its bearing on the phase-rule representation of the equilibria in the iron-carbon alloys. The diagram of Roozeboom was drawn up on the assumption that below, say, 1100° C. the stable system was martensite *plus* cementite, and not iron *plus* graphite. That, however, failed to account for the fact that on slow cooling, and more especially in presence of small quantities of silicon, it was found that graphite separated from the mixture. The question, therefore, arose as to whether Roozeboom's curve was to be discarded altogether, or whether some modification could be made to interpret facts which had been met with in studying the cooling of iron-carbon alloys. Under certain conditions the curves of Roozeboom did actually represent what was found, but with the slow cooling of the alloys and the presence of silicon they no longer represented the conditions which obtained. Undoubtedly, Roozeboom was wrong in his assumption that martensite and cementite formed the stable system. It appears quite certain from what Mr. Hiorus had said, and his results had been confirmed by other workers, that the stable system was formed by ferrite and graphite. Roozeboom's curves could still be applied to represent the conditions met with in the presence of manganese, by supposing that they represented metastable systems. That is to say, all the curves below the temperature of say, 1100° would represent conditions similar to what occurred in the case of glass, a supercooled liquid; and slow cooling, or the presence of silicon, prevented this supercooling, just as in slow cooling glass became crystalline or devitrified. It must be assumed that even in the absence of silicon, if the cooling were sufficiently slow, a mixture of ferrite and graphite could be obtained, since that was the stable system. Manganese, however, appeared to have the property of promoting supercooling, so that when manganese was present, the metastable system martensite *plus* cementite was obtained, and in that case Roozeboom's curves could be applied. Silicon acted in the opposite way, by practically preventing the supercooling. It acted catalytically and produced the stable system. Mr. Hiorus objected apparently to that explanation of the action of silicon by saying that he thought it required the formation of carbon silicide. That was not necessarily an objection, because it begged the question as to how the catalysis was effected. Almost infinitesimally small quantities of certain substances could produce marked effects, so that silicon present in less than 0.05 per cent. might produce a marked effect in facilitating the separation of the graphite. As far as the investigation has gone at present, Roozeboom's diagram could still be accepted if it were assumed, as had been pointed out by Heyn, that all the lines below the temperature of 1100° represented metastable conditions, i.e., they referred to supercooled carbon-iron alloy.

Dr. T. S. PRICE supported what Dr. Findlay had said with regard to Roozeboom's curve. At the annual meeting of the German Bunsen Society in 1904, Prof. Heyn read a paper in which he criticised Roozeboom's views, and brought forward a number of practical details which did not agree with Roozeboom's curve. Even above 1100° C. the metastable condition existed, as represented by martensite. He would also like to emphasise what Dr. Findlay had said about catalytic action. The theories of catalysis brought forward were often nothing but theories, and a way of getting out of a difficulty.

Mr. O. F. HUDSON said that when iron was cooled very slowly and a large quantity of graphite was obtained, that was the condition most favourable for the separation of graphite, which was very slow cooling through the eutectic point. Once graphite was separated in cast iron it was very rare for the amount of graphite to decrease. Indeed, slow cooling below the eutectic point (1130° C.) caused a further separation of graphite.

Mr. A. H. HIORUS, in replying, said with regard to what Prof. Turner had said about the quantity of graphite, he referred to the large flakes, which might be looked upon as the proper form of graphite. With regard to Mr. Buchanan's point about the effect of sulphur and man-

ganese, it was easy to understand that by adding manganese pig to sulphur pig a soft grey iron was produced, because the manganese united with the sulphur and both were then thrown out of the way. The iron might be cooled as slowly as desired with very little alteration below 1000°; it was by keeping the metal at a temperature somewhere between the dotted line and the black line of Roozeboom's curve that separation of the graphite was caused. That was the condition in the case of many large castings, which remained beyond 1000° C. for a considerable time and were a very long time in cooling; and the casting would be at the temperature at which the graphite could naturally separate. It could only be concluded that phosphorus was in solid solution, but iron phosphide in solid solution separated out during cooling. The separation of graphite must take place below the 1130° C., but on annealing cast iron for malleable castings, for example, the temperature was not raised to that degree. That was somewhere about 900° C.; graphite carbon separated out then, but never in the large flakes, only in the finely divided state. Mr. Rosenbain had given us some valuable information with regard to heat-treating. He agreed entirely with Dr. Findlay as to the metastable condition of cast iron. He thought he had brought out sufficiently clearly that if iron *plus* graphite was the stable condition all other forms were metastable or unstable conditions, therefore true equilibrium was only obtained when the cast iron was in the form of iron and graphite. He agreed with Dr. Price that the word catalysis could be used to explain many things, and with the very small quantities present, such as he had referred to, further evidence was needed before the view that the changes were due to catalytic action could be accepted.

Liverpool Section.

Meeting held on Wednesday, Dec. 13th, 1905.

MR. E. CARLY IN THE CHAIR.

FLOUR MILL EXPLOSIONS AND DANGEROUS DUSTS.

BY WATSON SMITH.

The investigation of dangerous dusts, that is, dusts composed of organic or carbonaceous matter in a fine state of division, was commenced by Faraday and Lyell in 1844, after the great explosion in the Haswell Collieries in September, 1844. They presented their report to the Home Secretary in 1845, and in this report they clearly indicate that an explosion of fire-damp, which in itself would not have been specially disastrous, might be exalted into a terrible and far-reaching catastrophe through the coal dust raised and carried along by the incipient fire-damp explosion. On Jan. 17, 1845, Faraday delivered a discourse in the Royal Institution, and he used these words:—"The ignition and explosion of the (fire-damp) mixture would raise and then kindle the coal dust which is always pervading the passages, and these effects must in a moment have made the part of the mine which was the scene of the calamity glow like a furnace." In spite of this discourse, and the report to the Home Secretary, and the fact of the report being published in the *Philosophical Magazine*, and followed by a letter from Faraday, in which he made suggestions as to the methods for ventilating the mines, but little, if anything, was done until further disasters in later years forced the subject into considerable prominence, and a Royal Commission was appointed, in which the late Sir Frederick Abel figured so prominently.

But there are many kinds of carbonaceous dusts besides coal dust; for example, flour dust, rice dust, soot, and lamp-black, also the dusts of sugar, and rosin, and finely divided

cotton, Garancine, &c. Mr. B. E. R. Newlands informs me that he has himself witnessed a sugar dust explosion in a sugar works. (See also Engler: this J., 1885, 486 and 487.) Engler bears testimony to the explosive character of soot and lamp-black when mixed with air. An explosion occurred in 1878, at the Garancine Mills at Sorgues, consequent on the ignition of a mixture of air with the Garancine dust. Cork, pulverised and sifted for linoleum manufacture, forms with air a mixture so inflammable and explosive that Mr. W. F. Reid declares he would rather handle dynamite in bulk than ground cork in a loose state (this J., 1896, 76). Cotton mills have become rapidly fired by the ignition of mixtures of cotton dust and air. As a partially carbonaceous substance, the dust of Prussian Blue, when mixed with air, has been known to flash off, whilst the cakes of blue were being ground by iron rollers, probably the presence of pebbles or stones causing sparks to be struck. As a non-carbonaceous substance it may be interesting to note that the inflammation of sulphur dust and air in pulverising chambers, has caused explosions. It only needs the use or occurrence on a sufficiently large scale of any of these or similar substances, dry and in a fine state of division, to give rise under suitable conditions to dangerous explosions. The truth of this remark is borne out in the case of flour dust, which, in the flour mills of this and other countries, has caused very many disastrous explosions. There were two reasons why these flour mill disasters were not earlier understood. The first was that their cause was obscure. The bare idea that flour might explode, on the face of it, appeared absurd. The second reason was that, until the larger flour mills of more modern times were erected, the explosions and fatalities were not sufficiently great, the ruin of life and property not on a sufficiently large scale to attract special public attention. But just prior to 1872, in Friedland (Germany) and Budapest (Hungary) where flour mills are specially numerous, so many serious fires and explosions had occurred, that the attention of a few scientists had been drawn to the subject; but little was done, and no authoritative or weighty publication made.

On July 9, 1872, a violent explosion took place at the Tradeston Flour Mills, near Glasgow, followed by a destructive fire. Eighteen persons were killed and 16 injured. The damage to property amounted to £70,000. A full report appeared in the *Glasgow Herald* of July 10, 1872. The *Herald* stated that at first it was supposed that the boilers had exploded, but subsequent investigation showed that some part of the machinery had gone, and the report adds, "probably the millstones, which were of great power and liable to explosion through excessive friction." This explosion, it is added, was characterised by the fire following, being of excessive ferocity, the flames shooting up 100 ft. high at times. Adjoining property was much injured. A surviving workman said "he had carried a lamp," so it is clear that open lights might at that time be used without any idea of danger, showing the ignorance then of any risk from the firing of a mixture of flour and air. The correspondence column of the *Glasgow Herald* also contributed additional proof of this ignorance. After seeing the announcement of the Tradeston explosion and having just read an anonymous article in *Dingler's Polyt. Journal*, I made an experiment and found that dry flour and air would fire like a mixture of lycopodium and air, and communicated my conclusions on July 10th to the *Glasgow Herald* (issue of July 12th), thus giving the true cause of flour mill explosions for the first time in English speaking countries. The Royal Society of Edinburgh recognised my priority in framing the letter referred to, and it was established by Sir F. A. Abel, F.R.S., in his lecture at the Royal Institution in 1882.

Immediately following my letter, the whole subject was investigated by Rankin and Macadam. The origin of the explosion was conclusively traced to the striking of fire by a pair of millstones through the stopping of the feed, and the consequent friction of their bare surfaces against each other. The flame thus produced, was quickly communicated to the mixture of dust and air filling the conduits connected with the exhaust box; this being the common receptacle

into which the mixture of dust and air is drawn by an exhaust fan through the conduit communicating with the several mills. From the exhaust box, where a portion of the suspended flour dust was deposited, the air, still laden with dust, passed in the Tradeston, as in other flour mills, to another room, called the stive room, where a further quantity of the flour would deposit. Hence, as Sir Frederick Abel clearly showed in his lecture at the Royal Institution in 1882, on "Some of the Dangerous properties of Dusts," there were here a connected series of chimneys and larger enclosed spaces filled with a dust-laden atmosphere, through which flame was so rapidly transmitted from the millstones, where the first ignition occurred, that violent explosive effects were produced, succeeding each other with great rapidity in different parts of the building. The production of the blaze at the millstones was observed to be at once succeeded by a crackling noise as the flame quickly spread through the conduits to the exhaust box upon an upper floor, whence a loud report almost at once proceeded. Rankin and Macadam's inquiries elicited the fact that other flour-mill explosions had been attended by a similar succession of effects to those just indicated. Sir Frederick Abel then points out that Rankin and Macadam ascertained that accidents of this nature at flour mills were of frequent occurrence, especially since the exhaust arrangements had been applied to the larger flour mills, and in their report it is added, that "it seems scarcely possible to guard against such accidents, though their frequency may be reduced by adopting efficient precautions for avoiding the stoppage of the feed to the millstones and the access of nails or other iron particles to the stones; also by prohibiting the employment of naked lights in the vicinity of the mills or dust passages." Various other suggestions are given of a similar character. But Sir Frederick makes now this important statement, viz., that "Since the publication of Messrs. Rankin and Macadam's valuable report, the accidents at flour mills appear to have been scarcely less numerous or disastrous than before the date of the Tradeston catastrophe." He then gives a series of illustrations of this fact both in America and in this country. Amongst these a great explosion occurred in 1878, at Minneapolis, Minnesota, where 18 lives were lost and six corn mills destroyed. The cause of the explosion was then traced by Professor Lawrence Smith to the same cause as that already given.

In 1881, the statement of Rankin and Macadam that "It seems scarcely possible to guard against such accidents," &c., seems still to be verified, for in September, 1881, a fatal flour mill explosion occurred at Macclesfield, Cheshire, and a report thereon was made to the Home Secretary by Mr. T. J. Richards, of the Board of Trade. The cause here was traced to (1) the use of a very dry grain, and (2) the accidental stoppage of the feed. The year after the Macclesfield explosion, February, 1882, an explosion occurred at Rochdale, in the exhaust room, through the stones striking fire. A fire followed, doing damage to the extent of £33,043.

Rankin and Macadam, and Prof. Lawrence Smith and T. J. Richards, only go so far as to show how disaster is liable to haunt any arrangement of flour mill plant known, up to 1882, and even later, and Sir Frederick Abel, in his lecture before the Royal Institution, goes no further than this. Even at this day, there still exist flour mills, conducted on the old type, and overshadowed by the same risks as in, and prior to, the year 1882. In the case of these the old statement of Rankin and Macadam, that "It seems scarcely possible to guard entirely against such accidents," is as true as ever.

But a further step has been more recently taken which enables flour to be milled with perfect immunity from danger, and this was taken by the late Henry Simon, C.E., of Manchester, through his introduction of the iron roller grinding system for flour into this country in place of stone grinding, and of applying the "cyclone" system of collecting flour dust, whereby he not only produced purer flour, but recovered in the dust—formerly causing danger of explosion and injury to the health of the workpeople inhaling it, besides waste,—a useful by-product serving as cattle-food. In a word, he abolished the old dust chambers or stive rooms for

collecting dust, and substituted a "cyclone" dust separator, which separates air and dust in a manner analogous to that by which the chemist separates a suspended solid from a liquid by decantation. By means of the centrifugal action of the "cyclone," the dust is thrown to the side of the cone, and glides down to the bottom, where it escapes into a suitable receptacle, whilst the air free from dust passes out, as shown in the diagram, at the top, and up a cowl in the roof.

To give a clearer idea of the thoroughly modern system of wheat cleaning prior to grinding, I have separated it into six numbered stages. Only the stage No. 3* was used in the old system.

(1) The grain, fresh from the threshing process, is at once sent over a separator, which mechanically removes foreign matters. Through this separator the grain passes to storage bins.

(2) Later on, when the wheat is to be used, it is drawn and passes over another separator, and thence through "cockle and barley cylinders," to remove all the so-called "cockle-seeds" and barley, and also small stones and gravel.

(3) It next passes through a wheat-scouring machine, working by suction, and through which the wheat is further aspirated and the fibre rubbed off the kernel and carried away ("bran").

(4) The wheat now passes through a washer and "stoner," where it is thoroughly washed and rinsed with water, and all stones, &c., removed, when it passes to a "whizzer," which, by centrifugal action, removes the bulk of the water still adhering to the outer surface of the wheat.

(5) The grain then passes into the drying and conditioning machine, where the remaining moisture is removed.

(6) Having passed through all these dry and wet cleansing processes, the wheat is finally sent through a double-brush machine, wherein, by means of the brushing action, a final mechanical polish is given to it, after which it passes to the magnetic separator, containing magnets which remove all metallic (iron) particles.

From the magnetic apparatus it passes to the first process of grinding; not by stones, however, but by specially hard and tough chilled iron rollers, fluted and smooth, and about 10 in. and 9 in. in diameter.

The fluted rollers, termed "break-rolls," are used to break down the wheat, and by means of the roller flutes, to scrape out the contents of the grains and separate them from the bran. The smooth rollers are used to crush into flour the particles of pure kernel detached by the

fluted rolls. The proportion of fluted rolls to smooth rolls is generally about four to six.

Now each individual machine referred to is subject to the action of strong currents of air so nicely adjusted as to energy, that whilst the kernels at any point remain or are balanced, the dust is carried away. Each machine is also covered in, and connected with the "cyclone" dust collector, which is constructed of iron and has air-tight joints. It will thus be seen that the "stive room," or dust-chamber, with its dangers, has vanished with the advent of the "cyclone dust separator." The dust from the "cyclone" is used, mixed with other bran or dust, as cattle food. Previous to this, such dust was a nuisance, a source of injury to health, and one of danger by fire or explosion. Flour mill insurance companies are fully awake to this, and reduce their insurance on the average to the extent of 2s. 6d. per cent., when such a "dust separating arrangement as that described is used instead of dust-chambers.

In Liverpool, this spring, there was a flour-mill explosion of considerable magnitude, followed by a fire, although the improved iron-roller system was in use, but instead of a "cyclone" or similar dust separating arrangement, there was, I am informed, a dust chamber or stive-room, and it was in this chamber that the explosion occurred. The system must be completed by the substitution of the cyclone separator for the dust chamber, to ensure freedom from peril, and preferably the whole mill should be electric lighted, and also furnished with automatic water-sprinklers, or similar water extinguisher, to at once stop any slight outbreak of fire.

I have referred to other dangerous dusts, and I may now add that any of these, in any of the industries concerned, may, as in flour mills, be suitably drawn off by exhaust arrangements, and then be driven into a cyclone separator and collected. Sir F. A. Abel's address to the Royal Institution on "Dangerous Dusts" was made in 1882, and Henry Simon's patent for utilising the cyclone separator for flour dust in flour mills was published in 1886. Simon also applied the "cyclone" system for the removal of emery dust and lamp-black from the atmosphere of certain of our largest furniture and "blackening" works, and for the economic recovery of the material.

H. Simon's patents are as follows:—

For roller mills and flour mills, Eng. Pats. 3725 of 1877; 2556 of 1879; and 2576 of 1879.

For cyclone dust collector, Eng. Pat. 9423 of 1886.

For roller mills and flour mill apparatus, Eng. Pats. 9746 of 1891; 28,716 of 1902; and 9704 of 1904.

DISCUSSION.

Prof. CAMPBELL BROWN said he could corroborate the date which Mr. Watson Smith had assigned to the beginning of their knowledge of the causes of explosions in flour mills. He had himself read a paper on the same subject to the Literary and Philosophical Society of Liverpool, after some rather bad explosions in large flour mills at the North End, an abstract of which was printed in the *Journal of that Society* dated 1873. He had illustrated the paper by means of large glass tubes and a box with Lycopodium seed. All they know then was that flour dust mixed with air played the same part as a mixture of air and coal-gas, or other inflammable gas, and one explosion in a flour mill was distinctly traced to the stoppage of the feed, which allowed the stones to come into contact with each other, to strike fire, and, in fact, act like a lucifer match lighted in a fiery coal mine. But among things they did not know then was how a length of pipe in the exhaust, or a series of chambers, or even of rooms through which the explosion passed caused a very great increase in the violence of the explosion as it went on from point to point, due to the successive impulses given to the explosion by the successive waves of vibration, each vibration being added on to the sum of the impulses of those behind them. Rankin and Macadam believed explosions to be inevitable, and wanted to prevent them becoming serious and to confine them to certain channels and get them out into the open air as

soon as possible. He was glad to hear that the use of the cyclone had been so effective in stopping explosions, for, long after the matter had been reported on by Rankin and Macadam, explosions in flour mills and coal mines went on as gaily as before, because people did not take the precautions sufficient to prevent them. Were there any statistics showing to what extent there had been a reduction in the number of explosions in places where one might expect to have them?

Mr. E. J. BATY said he had heard Prof. Bedson lay great stress on the point that coal dust explosions took place so readily because of the occlusion of gases on the surface of the coal. He himself thought that the tendency of an organic dust to explosion depended upon the united circumstances of, first, its fineness, and second, the volume of gases it could occlude upon its surface. Some dusts did not seem to occlude gases nearly as much as others. He would like to know if any one had ever tried to measure the amounts of gases which dusts of different degrees of fineness could occlude?

Mr. H. B. STOCKS having inquired whether Mr. Watson Smith could give them any particulars of ways of separating stive dust, other than those of the old stive room and the "cyclone" method, he proceeded to describe a method of passing the material by means of a fan into filter chambers, which were really long canvas bags, or, in some cases, a canvas receptacle shaped like a balloon. In the case in point, the dust remained practically in the canvas bags, just as though they were filters, and the air passed out through the canvas. Regarding the moistening of the grain, that was not done for the purpose of damping the dust, but to get the grain into good condition for grinding ("conditioning"). When the grain was too dry, the friction on the stones caused them to become glazed, and they did not grind nearly so well. If a certain amount of moisture was added to the grain, the grinding was very much easier, but the amount of moisture must not be excessive, or the stive flour then became a kind of pulp and spread itself round the casing of the stones. In grinding cereals, if this product was too moist to begin with, the moisture driven out of the grain formed a sour cake with some of the stive flour; if this was not cleared out of the casing of the stones from time to time, it eventually dried and fell back between the stones, and was ground up with the flour. When flour of that kind was stored in sacks out of contact with the air it fermented, and became sour in a very few hours.

Mr. CHARLES BURNE said he thought that in most modern mills at the present time two methods of dust separating were carried out, (1) the cyclone dust collector, largely confined to cleaning operations, and (2) the method of collecting the stive from the stones. The latest machine, of which numbers were now coming into this country, was of foreign make, and consisted of long canvas sleeves, which had been chemically fire-proofed. These were connected at the top with a box, sometimes metal lined and sometimes not, and the "stive" from the stones came into this top box, and was automatically made to go down into the canvas sleeves, whence it fell into a similar box at the bottom. There it was received and automatically conveyed to a sack—the sacks being removed as filled. He thought this machine had been found to supply a want; certainly amongst modern mills—and he had gone through some of the most modern mills, where it was recognised to be the most economical machine. The centrifugal action of the cyclone dust collector did not deposit the very finest stive; the canvas filters seemed to take out almost every particle of stive that was in the air. Reference had also been made to explosions being set up by friction due to stoppage of the feed. In one modern mill, where he had been quite recently, an ingenious device had been adopted for checking that danger. If the feed got below its proper amount, an alarm bell rang. If this bell were not attended to, the rollers were automatically thrown apart. With respect to the moistening

of the grain, it might be of interest to know that there were some mills where the moistening was done by the injection of steam. He understood also, from enquiries he had made from time to time, that the flour from this moistened or damped grain, was of better quality for baking purposes than flour which was not moistened at all; this was, of course, a reason for moistening in addition to that of lessening of friction between the rollers.

Mr. W. ROSCOE HARDWICK asked whether the production of a damper flour materially mitigated the explosibility of that flour?

Mr. A. CAREY referring to what Mr. Watson Smith had shown them with Japanese coal dust, asked whether experiments had shown how far the liability of coal dust to explosion varied with the per cent. of volatile matter present.

Mr. WATSON SMITH, in reply to Prof. Campbell Brown, said that only comparatively few flour mills in this country were now without the cyclone apparatus, and that a flour mill explosion to-day might be regarded as phenomenal. He could certainly say that where the stive room, &c., had been abolished, and the cyclone apparatus and iron rollers had together been adopted, no explosion had ever occurred. As he had already pointed out, he had been assured that the insurance companies reduced their terms to flour millers using the modern apparatus described. As to Mr. Hardwick's question about damping the flour, the true reason for this had been admirably explained by Mr. Stocks, and Mr. Burne. Beyond this, no doubt damp flour was less likely to fire than dry flour; its rising in dust would also be more limited. Also as regards the action of the old millers, prior to 1872, damping the grain before grinding, as he had mentioned, this was not to prevent explosions (about the nature and cause of which they knew nothing) but to "condition" the grain. He ought to add that any other dry carbonaceous powder, such as that of bran, was liable to explosion with air. In answer to Mr. A. Carey's question, he would say that in ordinary coal, i.e., the coal of the coal measures, the percentage of bituminous matter, soluble in benzene or naphtha, is so small, that the slight variations in different varieties would make no sensible difference in the inflammability of the dusts. There was no doubt in his mind that the Miké coal, the dust of which he had fired that evening, mixed with air, would explode more readily than any other coal dust. That Japanese coal was a lignite and contained upwards of 10 per cent. of resinoid matter, soluble in benzene, whilst ordinary coal never contained even as much as 1 per cent. (this J. 1891, 976). But no experiment with its dust like this, had been tried with the Miké coal before. The Miké mines were damp, lying, as they did, chiefly under the sea, but might be extended landwards where dry dust would abound and of a very dangerous nature. Prof. Bedson's idea about the occlusion of oxygen was a suggestive and interesting one, and he felt the probability of much truth in it, especially where the dust lay in the workings, with air continually passing over it by means of the ventilating system.

In reply to Mr. Burne, he said that whatever were the methods adopted, whether it were a cyclone arrangement or any other, mattered not, so long as the dust was effectively removed and disposed of. But how long would the bags referred to, continue to act as air-filters before getting choked? He would like to be sure that the porosity of the fire-proofed canvas of the bags in the new system referred to, was not, in part, choked by the fire-proofing mixture, and thereafter by the flour dust itself. As to the warning bell to automatically record a failure in feed-supply, and other automatic arrangements to separate the stones, automatic gear had often a trick of sticking fast or failing at a critical moment, and he preferred, in cases where human life, as well as property, was concerned, a revolutionising of the system to ensure safety.

(Continued from page 7.)

ENGLISH PATENTS.

Atomising Liquid and Gaseous Fluids; Means for —
C. F. de Kierzkowski Stenart, London. Eng. Pat.
27,618, Dec. 17, 1904.

A PLUG of truncated conical form, having on its face longitudinal grooves, is fitted into a conical seat at the outlet of a chamber into which the liquid to be atomised is supplied under pressure. The liquid issues from the grooves in a number of jets, which intersect at a common point, and becomes atomised. A modification is claimed in which the plug has in addition a central orifice, controlled by a needle-valve. The chamber may be divided into compartments so that two or more liquids may be mingled in the same jet. Further claim is made for an internal valve mechanism adapted to shut off the flow of liquid close to the point of discharge; and for a casing lined with refractory material and provided with air inlets, for use when the jet is employed as a burner for liquid fuel. W. H. C.

Heating, Cooling and Similar Purposes; Apparatus for — J. W. Claridge,
London. Eng. Pat. 28,197, Dec. 23, 1904.

THE claim is for the construction of heating or cooling boxes, which are divided by internal diaphragms into two or more compartments, through which the cooling or heating medium circulates successively. Two or more boxes may be connected together to form a system and placed in a chamber containing the material to be treated, or the material may be placed in the boxes and the medium circulated in the chamber. Further claim is made for constructing the boxes with external corrugations or projections, to increase the heating surface, or to assist in dislodging any deposit that may be formed on them, and for setting the boxes at an angle in the chamber, to promote circulation of the surrounding contents. —W. H. C.

Separation of Solids from Liquids; Impts. in — J. J. Crossfield, Frodsham, and K. E. Markel, Warrington.
Eng. Pat. 5108, March 11, 1905.

THE mixture to be separated is caused, by means of deflecting plates or baffles, to pass alternately up and down, but chiefly in a horizontal manner, through a passage or passages which are of increasing cross-sectional area. In this way the flow of the liquid becomes slower, as the heavier portions of the solids are deposited, and time is allowed for the lighter portions to settle out. —W. H. C.

Solvents; Process for Recovering Vapours of Volatile —
Soc. Jules Jeao et Cie., and G. Raverat, Paris. Eng.
Pat. 13,603, July 1, 1905. Under Int. Conv., Sept. 1,
1904.

SEE FR. Pat. 350,149 of 1904; this J., 1905, 1161. —T.F.B.

UNITED STATES PATENTS.

Separator; Centrifugal — J. J. Berrigan, East Orange, N.J., Assignor to F. J. Arend, New York, N.Y., and J. Bernstrom, Stockholm, Sweden. U.S. Pat. 807,055, Dec. 12, 1905.

THE liquid to be separated is fed into a rotating separator

through the annular opening C. The liquid portion escapes through the passage A formed between the end wall of the vessel and an annular lining piece, and the

solids are transported by the worm conveyor B to the other end of the separator, where they are discharged at E. —W. H. C.

Separator; Centrifugal — J. J. Berrigan, East Orange, N.J., Assignor to F. J. Arend, New York, N.Y., and J. Bernstrom, Stockholm, Sweden. U.S. Pat. 807,056, Dec. 12, 1905.

THE claim is for a cylindrical separating vessel 5, mounted on supports 2, 3, 4, so that the feed-inlet 12 is situated in a lower plane than the outlet 24 for the solids. The separated liquid escapes through the opening 21 formed in the lower end of the cylinder and the solids are transported by the worm conveyor 14 to the upper end of the cylinder and discharged through the opening 24. Both the cylinder and the drum are rotated at different speeds by the differential gearing, shown in the figure at 15, 16, 17, 18, 19, 20. —W. H. C.

Liquid-Separator; Centrifugal — C. M. Ketcham, Carthage, Mo. U.S. Pat. 808,092, Dec. 26, 1905.

THE separator consists of a long cylinder 2, having separable top and bottom pieces 11 and 3, which is mounted in an upright position in journals and rotated at a high speed by the wheel 26 and the worm gear 27. The liquid to be separated is fed from the store-tank D through the tube below, on to the spreader-plate 17, and is forced to partake of the rotation of the drum 2 by the action of the distributing vanes 13; 15 is a vent tube. When the liquids reach the bottom of the cylindrical portion of the drum 2, the heavier one passes down the annular space between the detachable cone 3 and the inner skimming funnel 19, out of the openings 5 and away by the spout 9. The lighter liquid flows over the edge of the funnel 19, down the central space 18, into the hollow cylindrical

prolongation 3', out of the opening 6 and away by the spout 10.—W. H. C.

Filtering Liquids; Device for ——. G. Stadel, Berlin. U.S. Pat. 807,513, Dec. 19, 1905.

SEE FR. Pat. 340,322 of 1904; this J., 1904, 779.—T.F.B.

Distilling Apparatus. J. Perout, Cleveland, Ohio. U.S. Pat. 807,577, Dec. 19, 1905.

A STILL, resting in a water-bath, is supported over a furnace, the joint between the still and the water-bath being made by a turned down flange on the still. The still has a still-head communicating with a condenser and formed by a dome-shaped piece and an inverted cone, which fits over the outside of the neck of the still. A diaphragm is fastened across the still-head, underneath the dome, and has a vapour-pipe which telescopes into the neck of the still. The claim is for the combination of the foregoing parts to form the whole distilling apparatus as described.—W. H. C.

Measuring Vessel for Liquids ——. H. C. Dehn. Hamburg, Germany. U.S. Pat. 807,665, Dec. 19, 1905.

THE liquid to be measured is stored in a reservoir *a*, which communicates by the conduit *b* with the measuring vessel *c*. The latter is a rotatable tank, divided into a number of separate chambers, two of which, *d* and *e*, are shown. The liquid flows down the pipe *b* and rises up into the chamber *c*, the air escaping by the pipe *f* into the hooded outlet *g* in the reservoir *a*. Simultaneously the opposite chamber *d* is being emptied, the liquid flowing out through *i*, and air entering through *h* to displace the liquid. At each turn these operations are continued, one chamber being emptied while the opposite one is filling. The measuring chambers have overflows *k*, covered by an inspection dome on the top of the measuring vessel.

—W. H. C.

Evaporating Apparatus; Vacuum ——. C. Ordway. New York, N.Y. U.S. Pat. 807,767, Dec. 19, 1905.

THE concentrated liquor is withdrawn from the bottom of the evaporating chamber by a pump, and is delivered into the upper part of one or other of several closed settling vessels, care being taken, by guarding the inlet, to avoid disturbing the contents of the settler. The settled liquor is withdrawn from the upper part of the settler and is either returned to the evaporator, or is delivered to another vessel for subsequent treatment. The settlers are provided with screens to receive any deposited solids, with taps for breaking the vacuum, and with valved drain pipes at the bottom to draw off the liquor when it is necessary to remove the deposited solids.—W. H. C.

Drying Apparatus. F. M. Schaffer, Indianapolis, Ind. U.S. Pat. 808,481, Dec. 26, 1905.

THE apparatus consists of a horizontal cylinder through which the material to be dried is passed by an internal worm conveyor. The cylinder is suspended and rotated in a chamber above a furnace by means of chains, which pass round sprocket-wheels fixed to the cylinder, and over corresponding sprocket-wheels attached to a horizontal driving shaft situated above the chamber. The feed end of the cylinder is provided with a "breeceling" which carries the feed hopper and shoot. The gases from the furnace may pass through the cylinder or direct to the flue as desired, and the driving-chains are protected by covers from the action of the fire and hot gases.—W.H.C.

GERMAN PATENT.

Drying Process, in which the Material to be Dried is Subjected to the Action of Light Rays. A. Junghans. Ger. Pat. 162,686, Sept. 23, 1904.

THE claim is for drying substances while exposing them to suitable coloured rays, in order to avoid injurious effects (decomposition, discoloration, &c.), and to accelerate the drying. It is stated that the drying process is sometimes slow with white light, and that injury is occasionally caused, the reason being that many of the light rays are inactive so far as drying effect is concerned, whilst some rays may cause decomposition. For example, sugar which is nearly dry becomes liquid again on exposure to red light. In the drying process, light of a suitable colour should be used for each kind of material; frequently the most suitable colour is that which is reflected to the greatest degree by the material in question. For example, sugar can be rapidly dried in blue light, without liquefying or being injured in any way. Blue enamel-paint dries rapidly without alteration of colour in the mixed light from "white and blue incandescence lamps," whereas in the light from an arc lamp, the drying proceeds more slowly and the colour is said to change to green.—A. S.

II.—FUEL, GAS, AND LIGHT.

(Continued from page 12.)

Naphthalene from Coal Gas; Removal of ——. A. H. White and D. H. Clary. J. Gas Lighting, 1905, 92, 388—393; 466—468.

IN studying the question of naphthalene removal in gas-works, experiments were made on the absorptive power

of various tars for naphthalene at different temperatures. About 1 grm. of the tar was placed in a 1 oz. wide-mouthed bottle, in which also a small glass thimble containing naphthalene was placed on a wire tripod. The bottle, with the stopper wired on, was kept at a constant temperature until the tar was fully saturated with naphthalene. It was found that tars of different origin vary considerably in their power of absorbing naphthalene, and also that the amount of naphthalene taken up by a given tar increases with rise of temperature. For example, the averages of all the tests showed the following percentages of naphthalene in the fully saturated tars:—25° C., 9.1; 35° C., 16.7; 45° C., 21.1; and 72° C., 48.7 per cent.

Further experiments were made as to the proportions of naphthalene in the tar and in the gas at the top of the stand-pipe, before and after passing the Pelouze and Audouin tar-separator, and before and after passing the scrubbers. From the results obtained, the authors conclude that in the hot stand-pipes and warm hydraulic and foul mains, the naphthalene is readily absorbed by the tar, and, provided enough time is given to this stage of the process, the gas will arrive at the tar-separator free from any measurable amount of naphthalene other than that held dissolved by the suspended tar. In the tar-separators, the particles of tar still exert a solvent action on the naphthalene in the gas, but not to so great an extent as in the hotter stand-pipe and mains. In the scrubbers, the water removes the lust of the suspended tar and likewise the ammonia, and some other constituents. But the ammonia, as was proved by direct determinations, dissolves some of the phenols from the tar, and since these phenols are good solvents of naphthalene, some of the naphthalene dissolved in the tar becomes liberated and is then taken up mechanically or as vapour by the gas. This liberation of naphthalene by the action of ammonia in the scrubbers is considered to be the most frequent source of naphthalene trouble.

For the prevention of naphthalene stoppages, the authors suggest that the foul main be made large so that the gas will be kept hot until the tar has had time to remove the naphthalene; and also that care be taken to remove the tar as completely as possible before the gas passes to the scrubbers. If the gas after leaving the scrubbers still contain naphthalene, probably the most convenient method for its removal is that of scrubbing with tar or tar distillates.—A. S.

Naphthalene from Coal Gas; Removal of — H. G. Colman. *J. Gas Lighting*, 1905, 92, 526, 596 and 672.

In their recent investigation of this subject, White and Clary (see preceding abstract), among other conclusions, put forward the hypothesis that a more complete removal of naphthalene from gas is effected by washing the latter with hot tar, than by the action of the same tar when cold, basing their view on direct determinations of the amount of naphthalene taken up by tar at varying temperatures, and also on the results obtained from the estimation of the amount of naphthalene in crude coal gas at various points in the condensing system of gas works. The first-named experiments, however, under the conditions employed by White and Clary, simply show that hot tar will absorb more naphthalene from gas than the cold tar, provided that the gas is saturated with naphthalene at the same temperature, and in no way indicate that the amount of naphthalene left in the gas is less when the tar is hot, but rather the reverse. The method adopted to determine the amount of naphthalene vapour in the crude gas, as distinct from the naphthalene contained in the tar mechanically suspended in the gas, gives figures below the true value, inasmuch as the filter used for separating the tar-fog also absorbs some of the naphthalene present as vapour in the gas, and no valid conclusions can therefore be drawn from these experiments.

Further, White and Clary's hypothesis is quite inconsistent with other known facts. If true, it would follow that the vapour pressure of naphthalene dissolved in coal-tar must decrease with increasing temperature, and, therefore, that gas free from naphthalene passed through such tar would take up smaller quantities of

naphthalene with rising temperature, and also that on distillation, the quantity of naphthalene in the distillate would decrease as the temperature of distillation rose towards the boiling point of naphthalene. In actual practice, however, exactly the reverse is the case.—H. G. C.

Naphthalene from Coal Gas; Removal of — W. Young. *J. Gas Lighting*, 1905, 92, 742—743.

White and Clary (see preceding abstract) state that the weight of naphthalene that can be dissolved by tar is about five times as great at 72° C. as at 21° C., and they conclude, therefore, that for the purpose of naphthalene removal, it is more advantageous to scrub the gas with hot than with cold tar. The author points out, however, that the rate at which naphthalene vapour is taken up by coal gas increases with rise of temperature much more rapidly than does the absorptive power of the tar. Since, therefore, the relative proportions of naphthalene in the gas and in the tar at a given temperature, depend upon the equilibrium between the powers of the gas and tar respectively of taking up naphthalene, the capacity of tar to absorb the naphthalene from the gas must fall with increase of temperature, and not rise as stated by White and Clary.—A. S.

Gases; Portable Apparatus for the Analysis of Flue — C. J. Wilson. XXIII., page 91.

Acetylene; Reaction of — on Iodic Anhydride. G. F. Janbert. XXIII., page 91.

ENGLISH PATENTS.

Peat Briquettes and the like; Process of and Apparatus for the Manufacture of — O. W. K., J. W., and G. O. Stronge, Elmsbetheln, Germany. Eng. Pat. 1947, Jan. 31, 1905.

Section through A A.

THE peat, after being thoroughly mixed so that it is uniformly moist, is delivered by the trough x into the

space between two channels a, a , which have conveyor bands c provided with plates b . The conveyors spread out the peat along the channels a, a , in the direction indicated by the arrows, and the whole machine is moved forward in a direction at right angles to its length by the motor r , to which it is fastened by the chains, g, g, g , leaving the mass of peat spread out uniformly over the ground. The conveyor plates b are bent slightly back at their lower ends and are guided by the projections shown at f, g , (Fig. 1), so that the chain may not sag and cause the layer of peat to be of variable thickness. The front walls a^1 of the channels are attached to carriages m by the arms l , and are deeper than the rear walls a^2 . These carriages serve to support the channels, and they are provided with screws and nuts to enable the height of the channels above the ground to be regulated. The layer of peat after being spread out is compressed by the heavy platform p , attached to the rear walls a^2 of the channels a .—W. H. C.

Atomising Liquid and Gaseous Fluids; Means for —.
[Burner for Liquid Fuel.] C. F. de Kierzkowski
Stenart. Eng. Pat. 27,618, Dec. 17, 1904. 1., page 58.

Gases; Centrifugal Apparatus for the Purification of —.
Applicable also for the Absorption of Gas by Liquids, and for other purposes. P. Kestner and A. J. Laversedge,
London. Eng. Pat. 29,178, Dec. 31, 1904.

A HORIZONTAL disc b , provided with vanes c, c^1, c^2, c^3 , and mounted on the spindle a , is rotated in the casing d , which has preferably the form of a truncated cone. The gas enters the apparatus at e , and, following the direction indicated by the arrows, leaves at f . Any liquid contained in the gas, or steam or liquid introduced through F or E for the purpose of purifying it, is driven by the centrifugal action of the vanes on to the walls of the casing d , and escapes by the pipe G . The claim is for the use of the revolving disc and vanes for separating and not for propelling the gas, and several modifications are claimed. The disc b may be fixed by brackets to the casing and the vanes only attached to the spindle; two or more sets of discs and vanes may be used in series, and a disc, having studs on its upper surface which revolve among other studs projecting from the top of the casing, may be used to ensure the contact of the gas and liquid. The distribution of the treating liquid may be effected either by feeding directly on to the vanes or it may be directed into

a distributing pan or dish with perforated sides or on to a flat disc or discs, the dish or discs being fixed on the rotating spindle above the separating vanes. An ordinary fan or its equivalent may be employed to produce the necessary movement of the gas.—W. H. C.

Photometers or Apparatus for Testing the Intensity of Light, comprising the use of a Selenium Cell. T. Torda and V. Bornand. Eng. Pat. 4620, Feb. 27, 1905. XXIII., page 91.

UNITED STATES PATENTS.

Fuel; Artificial — [from Garbage]. E. C. May,
Assignor to National Garbage Fuel Co., Chicago.
U.S. Pat. 807,629, Dec. 19, 1905.

By this invention, the stack made from prepared garbage is combined with an agent consisting of "oil" and hydrochloric acid, combined in the proportions of about 3 per cent. of "oil" and 0.5 per cent. of acid.—W. C. H.

Peat [for Making Fuel]; Process of Treating Raw —.
C. Schlickeysen, Steglitz, Germany. U.S. Pat. 807,088,

Coke and Gas Plant. V. G. Apple, Dayton, Ohio.
U.S. Pat. 807,532, Dec. 19, 1905.

THE plant described, consists of two batteries of horizontal retorts arranged side by side, with sufficient space between them for a boiler and steam engine, the power of the engine being employed in driving the mechanical feeding arrangements. The material to be introduced into the retorts is delivered from a source of supply arranged centrally relative to the retorts, and means are provided for transferring the material to each retort. The inlet openings of the retorts are provided with receptacles which are kept full by the transfer mechanism and means are provided for passing the material from the receptacles to the retorts, and passing it through them to the outlet openings. The outlet openings of the retorts for the coke communicate with a water-jacketed coke receiver, and the steam generated in the jacket can be supplied to the engine. The retorts are adapted to constantly receive carbonaceous material at one end, and discharge it at the other; a primary ascension-pipe communicates with the retort adjacent to the receiving end, and a secondary ascension-pipe communicates with the retort at a point relatively remote from it, and a pipe connects the primary ascension-pipe with the retort at a point relatively remote from the receiving end. To this connecting pipe, between the gas outlet and gas inlet of the retort, steam may be supplied from the water-jacket of the coke-receiver, and air under pressure may also be supplied. The retorts, with their heating means, are mounted upon a built-up base, in which is a transverse flue, substantially below the outlet ends of the heaters. Passages conduct heated air from the retort furnaces to the flue, provided with a central outlet, by which the heated air escapes and communicates its heat to a boiler arranged in its path.
—W. C. H.

Gas-Producer. B. Graupe, Cologne-Deutz, Germany.
U.S. Pat. 807,071, Dec. 12, 1905.

THE producer described is one with upper and lower combustion zones, and with means for withdrawing the gas from an intermediate point. A vertical grating, composed of vertical bars, forms part of the producer walls, through which gases are led off. Two annular evaporating chambers are arranged, one surrounding the top, and the other the bottom of the grating; one of the chambers is connected to an air supply, and means are provided for connecting the other with the interior of the producer, and for connecting the two chambers. The

producer may have an open hand-hole at the top through which air enters it, and by which access may be had to the grating.—W. C. H.

Gas-Producer. W. H. Bradley, Bellevue, Pa. U.S. Pat. 807,594, Dec. 19, 1905.

THE producer described is provided with a water-trough, across which is an inclined wall, and above this one or more wind-pipes extending along the producer in the direction of the trough; each pipe has clearance spaces on both sides for the removal of ashes. The wind-pipe is composed of cast-metal sections, having a horizontal top and both internal and external strengthening flanges.—W. C. H.

Gas-Producer. E. Körting, Hanover, Germany. U.S. Pat. 808,244, Dec. 26, 1905.

THE body of the producer *a* is fed with fuel from the hopper *b*, which is kept partly full to prevent the introduction of air at this point. The main air supply is furnished through the opening *d* in the door *c*, *f*, and enters the generator through the vertical grate *e* in the front of the producer; an auxiliary vertical grate *a*, supplied with air through *g*, is situated near the top of the producer. Any gas generated near the top passes along the channel *s, r, t*, to the main body of fuel just above the grate *c*. The producer-gas leaves the generator at the bottom by a vertical grate *u*, situated well below the horizontal plane of the grate *c*, and also by the openings at the sides of the ash plate *m*; it then passes along *l* to the outlet.—W. H. C.

Gas-Generator. H. A. Hartman, Philadelphia, Pa. U.S. Pat. 808,365, Dec. 26, 1905.

A TAPEING elbow-shaped retort *A* is set in a furnace *E*, and is connected with the hydraulic man *M* by the pipes *L*. The fuel is fed into the "water-receiving" hopper *G*, and introduced into the charging end *B* of the retort *A* by the conveyor *J*. The main portion *F* of the

retort passes through the furnace *E* in an inclined direction as shown, and is continued downwards outside the furnace by the pipe *G*, which dips into the water in the discharging tank *H*.—W. H. C.

FRENCH PATENTS.

Carburetted Air; Apparatus for —. A. Louis. Fr. Pat. 357,347, Aug. 30, 1905. Under Int. Conv., Oct. 11, 1904.

THE apparatus described consists of a vessel, open at the top, and filled with "liquid." Inside the vessel is mounted a rotatable drum on a horizontal axis, the means for driving which are arranged inside the vessel, *e.g.*, a pair of bevel-wheels, the driving shaft of which passes vertically up through the open top of the vessel, thus dispensing with gas-tight stuffing-boxes, &c. The drum is separated from the atmospheric air by a cover which dips into the liquid in the vessel. —W. C. H.

Barium Carbide and Metallic Manganese; Reduction of Barium Manganate in order to obtain —. C. M. J. Lamb. First Addition, dated Aug. 22, 1905, to Fr. Pat. 304,720, Oct. 20, 1900. VII., page 72.

Carbon Filaments for Incandescence Lamps; Manufacture of —. Cie Franc. pour l'Exploitation des Procédés. Thomson-Houston. Fr. Pat. 357,254, Aug. 26, 1905.

THIS invention includes the discovery and method of manufacture of a new substance (an allotropic form of carbon) for electric incandescence lamps. The filaments are superheated in an electric tube furnace, and after this treatment the electric resistance of the cold filament is diminished, and the coefficient of variation of resistance with temperature becomes positive. These filaments are stated to be more efficient and to last longer than the ordinary ones. (See also Eng. Pat. 6959A of 1904; this J., 1905, 721; also Eng. Pat. 6959 of 1904; this J., 1905, 882; and Fr. Pat. 349,857 of 1904; this J., 1905, 884.) —W. C. H.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(Continued from page 13.)

[Petroleum] Kerosene; Technical Requirements of Reagents for the Purification of —. K. Chantschikow. Westnik shirow. wechtsch. 1905, 6, 119. Chem. Rev. Fett- u. Harz- Ind., 1906, 13, 15.

THE colour of kerosene bleached by treatment with sulphuric acid is very injuriously affected by the presence of nitrous acid, of which as little as 0.02 per cent. produces a marked effect. Nitric acid is also objectionable, but 0.05–0.07 per cent. may be present without serious injury. Organic matter in the sulphuric acid is without appreciable effect.—M. J. S.

ENGLISH PATENT.

Ammonia from Distillation Gases; Extraction of —. R. Brnck, Dortmund, Germany. Eng. Pat. 15,646, July 31, 1905.

FRENCH PATENTS.

Ammonia, from Distillation Gases: Process of Recovering By-Products, especially —. H. Koppers. Fr. Pat. 356,600, Aug. 2, 1905.

THE gases are first cooled to 40°–45° C., whereby the moisture is condensed carrying with it about one half of the free ammonia, and including all the combined ammonia. The tar having been removed, the purified gases are reheated, preferably by utilising the heat of the crude gases from the retorts, and passed through acid in suitable scrubbers. The condensed water is mixed with lime and distilled with steam, the gases evolved being passed into sulphuric acid at a temperature sufficiently high to ensure that no condensation of water in the acid takes place. The residue in the still contains small quantities of phenols, &c., and it is proposed to project this, in a finely sub-divided condition into the chimney gases, the heat of which, it is stated, is more than sufficient to volatilise the whole of such residue. The gases, freed as above from ammonia, are then passed into a cooling apparatus, where the remainder of the moisture is condensed in the form of water which, it is stated, is pure. The resulting gases can then be treated in the usual way for the recovery of benzene, &c.—T. F. B.

Petroleum and its Homologues: Method of Saponifying —. F. J. Lothammer and C. Trocquenet. Second Addition, dated Aug. 19, 1905. (Under Int. Conv., Aug. 18, 1905), to Fr. Pat. 338,636, Oct. 10, 1903; this J., 655.

EQUAL parts of an aqueous extract of quillaja (density 6° B.) and petroleum are mixed to an emulsion, which is brought to the consistence of gelatin by further additions of petroleum if necessary. The resulting gelatinous mass is next ignited on a sloping table, and the heavy oil, which separates out during the operation, runs down the table and is collected. Then 277 kilos. of solid vegetable oil (cocoanut, palm, arachis, &c.) are gently heated with 117 kilos. of the recovered oil, and treated with 270 litres of caustic soda lye of 12° B., followed by 306 litres of 20° B. strength. The whole is boiled for about three hours until homogeneous, whereupon the mass is treated with 38 litres of potash lye (20° B.), and 10.8 kilos. of pale resin, heating being continued until a test sample sets on exposure to the air. Finally, the mass is run into moulds and cut into blocks or cakes.—C. S.

Candles: Manufacture of Composite Paraffin —. Standard Oil Co. Fr. Pat. 357,507, Sept. 5, 1905.

SEE U.S. Pat. 802,100 of 1905; this J., 1905, 1166.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

(Continued from page 14.)

Pyridine Dyestuffs from Furfural: Production of —. W. König. J. prakt. Chem., 1905, 72, 555–562.

WHEN 1 mol. of furfural is heated for a short time in alcoholic solution with 2 mols. of an aromatic amine, and 1 mol. of an acid, diluted with alcohol, is added after cooling, crystalline dyestuffs are precipitated in an almost chemically pure state. They show considerable affinity for unmoistened vegetable fibres. They crystallise with 1 mol. of water, which seems to be constitutional, but can be removed by carefully heating *in vacuo*, and in some cases by recrystallisation from glacial acetic acid. By heating the anhydrous products so obtained from primary amines above their melting-point, or by heating them with acids, they are decomposed forming 1 mol. of a primary amine and 1 mol. of an aryl-β-hydroxypyridonium salt of the formula $C_5H_4(OH).NXR$.

From this fact, together with the empirical formulae of the various products, the author supposes the hydrated dyestuffs to have the formula:—

the dehydrated products having the formula:—

In these formulae R represents an aryl radical, R^1 an alkyl radical or hydrogen atom, and X an acid radical. The dyestuffs formed from furfural with aniline and with *p*-phenetidine were closely investigated. For example, 18.6 grms. of aniline were dissolved in 75 c.c. of alcohol and heated for 15 minutes on the water-bath with 9.6 grms. of furfural. 17 grms. (± 14.7 c.c.) of concentrated hydrobromic acid which had been previously diluted with 10 c.c. of alcohol were then added with cooling. The liquid congealed almost instantaneously to a paste of violet-red needles, which were filtered off and washed with ether, 22 grms. of almost pure dyestuff being so obtained. It can be purified by recrystallisation from acetic acid, and has then the m.pt. 164°–165° C. It dyes silk and tannin-mordanted cotton in deep red shades, and unmoistened cotton in pink shades. Its formula is $C_{17}H_{19}O_2N_2Br$. On heating with nitrobenzene it yields phenyl-β-hydroxypyridonium bromide,

The corresponding dyestuff from *p*-phenetidine dyes silk and tannin-mordanted cotton in fine rhodamine shades, which are not fast. Coloured products were also obtained with *m*- and *p*-nitraniline, but differed slightly in properties. The author has also obtained dyestuffs crystallising in bluish-green needles and soluble in alcohol with a pure blue colour by the interaction of furfuralacrolein,

with aniline and with monomethylaniline, but the yields were extremely small. The products are very unstable, but the author thinks that further investigation will confirm his view that they possess the constitution

$C_6H_5.N(CH_3).CH : CH.CH : C(OH).CH : CH.CH : N(CH_3).X.C_6H_5$ respectively.—E. F.

1,3,6-Trihydroxynaphthalene. R. Meyer and E. Hartmann. Ber., 1905, 38, 3945–3956.

ON melting 1,6-dihydroxynaphthalene-3-sulphonic acid with alkalis in an open vessel at a temperature not exceeding 270° C., 1,3,6-trihydroxynaphthalene is obtained according to Ger. Pat. 112,170 of 1899. According to the same patent the 1,3,6-trihydroxynaphthalene so obtained exists in two forms. The product obtained directly melts at 95° C., is easily soluble in cold water, and combines readily with diazo compounds to form azo dyestuffs. On recrystallising from hot water this is converted into a compound, of the same percentage composition, which does not melt, but decomposes at about 304° C. The patentees consider that this may represent a diketone-form. The authors, in the course of their investigation confirm the experimental results of the patentees, but bring further experimental data leading to other theoretical conclusions. Both the original trihydroxynaphthalene and its transformation product form triacetyl- and tribenzoyl-derivatives of identical composition, but different properties. The transformation product does not react with other phenylhydrazine or hydroxylamine. These facts show that the original substance is not transformed into a ketonic isomeride. Molecular weight determinations of the transformation product and of its acetyl- and benzoyl-derivatives led to bimolecular formulae $C_{20}H_{16}(OH)_3$, $C_{20}H_{16}(O.OC_2H_5)_3$ and $C_{20}H_{16}(O.OC_2H_5)_3$, whilst the product directly obtained and its corresponding derivatives agreed with the formula $C_{10}H_6(OH)_3$. The product obtained directly easily forms addition compounds both with water and with hydrochloric acid, which dissociate very easily. The authors come to the conclusion that these are oxonium derivatives of a quinoid keto-form, such as

that in aqueous solution both the trihydroxy- and the keto-forms are present, and that the transformation product is formed by a kind of aldol condensation and has some such formula as:—

being a hexahydroxydihydrodinaphthyl. In preparing 1,3,6-trihydroxynaphthalene on the laboratory scale it was found necessary to use about twice the amount of alkali hydroxide which is mentioned in the German patent. For instance, 25 grms. of the sodium salt of 1,6-dihydroxynaphthalene-3-sulphonic acid were added gradually to 80 grms. of sodium hydroxide contained in a silver dish, which was heated over a gauze with an ordinary Bunsen burner. When the water of solution had evaporated, the temperature attained 200° C. The melt then gradually darkened until, at 250° C., the reaction took place with frothing and evolution of steam. It was finished when a sample dissolved in a little water, acidified with hydrochloric acid and shaken up with ether, was almost decolorised, all the yellow product being taken up by the ether. The melt lasted about three hours. The product was dissolved in a little water, strongly acidified with hydrochloric acid, the liquid filtered whilst hot and allowed to cool. Yellow needles of the hydrochloride of trihydroxynaphthalene were so obtained and were purified by recrystallisation from hydrochloric acid with a little animal charcoal. By digestion with a little water it is converted into colourless crystals of 1,3,6-trihydroxynaphthalene, which may be recrystallised from hot water if this is quickly cooled to avoid polymerisation. The polymeric product is obtained by repeatedly heating the trihydroxynaphthalene with water and animal charcoal to the boil, fresh quantities of animal charcoal being added each time. The polymeric compound crystallises out in white laminae. Both 1,3,6-trihydroxynaphthalene and its polymer, yield red dyestuffs by combination with diazobenzene chloride. The compound from trihydroxynaphthalene has the formula $C_{10}H_5N_2 \cdot C_{10}H_4(OH)_3$. Attempts were made to obtain one of the three dinaphthyls by distillation of the polymer ($C_{20}H_{10}O_6$) with zinc dust. A crystalline product, yielding fluorescent solutions, was so obtained, but not in sufficient quantity to be identified.

—E. F.

Hydroxyanthraquinones; Reduction Products of —.
M. Prud'homme. *Rev. Gen. Mat. Col.*, 1906, 10, 1-3.

ALIZARIN (0.5 gm.) was dissolved in a solution of sodium hydroxide (1 gm.), and 3 grms. of hydrochloric acid, 100 grms. of water and 5 grms. of zinc were added. Reduction was complete in about 10 minutes and a brown compound resulted, which dissolved in sodium hydroxide to a much redder solution than alizarin. It dyes mordanted fibres similar shades to alizarin from neutral baths, but from acid baths it only gives feeble dyings on iron and chromium mordants. If, instead of isolating the above brown compound, a further 4 grms. of hydrochloric acid and 50 c.c. of water be added, and the reaction allowed to proceed for about 20 minutes, a green compound is produced; when boiled with water, it is reconverted into the brown compound, with loss of hydrogen: its dyeing properties are similar to those of the brown compound. If either of these compounds is treated with a little dilute acid, it is converted into a yellow substance (with evolution of hydrogen, if prepared from the green compound), which is similar to alizarin in appearance, but its dyeing properties resemble those of the substances from which it is produced. When oxidised in presence of ammonia and treated with acids, all three compounds give a deep violet dyestuff, isomeric with that produced by oxidising

the compound which Roemer obtained (Ber., 1881, 1260) by reducing alizarin with zinc dust and ammonia: this latter has been proved to be identical with alizarinimide (produced by heating alizarin, under pressure, with a solution of ammonia in absolute alcohol). The three reduction products of alizarin are therefore considered to be:

Anthrapurpurin, when reduced by boiling with zinc dust and ammonia, gives two different colouring matters, very similar in properties to those obtained from alizarin. Flavopurpurin, on the contrary, only gives dyestuffs which dye mordanted fibres similarly to flavopurpurin itself. — T. F. B.

ENGLISH PATENTS.

Anthracene Derivatives and Dyestuffs therefrom; Manufacture of —. A. Meyenberg, C. Weizmann and The Clayton Anthrac Co., Ltd., Manchester. Eng. Pat. 8744, April 25, 1905.

Products which it has not hitherto been possible to manufacture on a commercial scale are obtained by the action of dry chlorine on anthracene in the presence of lead peroxide at a high temperature. For example, a mixture of 50 parts by weight of anthracene and 10 parts by weight of dry powdered lead peroxide is treated with dry chlorine at 220° C. until the weight has increased to a total of 120 parts. The temperature may, however, be varied, good results being obtained at from 180° to 260° C. The composition of the melt varies with the temperature employed and amount of chlorine absorbed. The product consists mainly of two portions, namely, β -tetrachloroanthracene, m. pt. 152° C., already described by Lieberman and Landmann (Ber., 13, 1589), which is readily soluble in benzene and crystallises out in yellow needles, and another portion, much less soluble in benzene, and more highly chlorinated. This second portion can be separated by fractional crystallisation into two products, one being hexachloroanthracene, melting at 277° C., which crystallises from nitrobenzene, and the other heptachloroanthracene, m. pt. 232° C., which is more soluble in benzene than the former. All these chloroanthracenes are transformed on oxidation into chloroanthraquinones containing two chlorine atoms less, from which it appears that the original products are chlorinated mesodichloroanthracenes. If, for example, a mixture of 10 parts of anthracene and 1 part of lead peroxide is treated with chlorine at 240° C. till it increases in weight by 15 parts, the melt consists almost entirely of the more highly chlorinated products. The above-mentioned tetrachloroanthracene reacts violently with a mixture of concentrated sulphuric and nitric acids, and, on pouring the product of reaction into water, a dichloromononitroanthraquinone is separated, which crystallises in almost white needles, soluble in nitrobenzene, and melting at 300° C. If the sparingly soluble portion of the melt is treated in a similar manner, the hexachloroanthracene yields a tetrachloromononitroanthraquinone, whereas the heptachloroanthracene is merely oxidised to pentachloroanthraquinone, melting at 325° C. On treating the above-mentioned nitro compounds with fuming sulphuric acid, with or without the presence of boric acid, dyestuffs are formed. In the case of mononitrodichloroanthraquinone, this reaction takes place at the ordinary temperature, whilst in the case of the tetrachloro compound, a higher temperature is necessary. — E. F.

Nitro-Derivatives of Certain Aromatic Bases; Manufacture of —. C. D. Abel, London. From Actienges. für Anilin-Fabrikation, Berlin, Germany. Eng. Pat. 9074, April 29, 1905.

In Eng. Pats. 6741 and 27,497 of 1904 (this J., 1905, 103

and 1257) there is described a method of manufacturing munonitro derivatives of aromatic bases by heating the arylsulphamino derivative of the base with dilute nitric acid. According to the present invention this process is applied to the nitration of *m*-diamines of the benzene or naphthalene series. The diarylsulphamino derivative of such a *m*-diamine is nitrated by the action of dilute nitric acid in the *p*-position to one of the arylsulphamino-groups. For instance di-*p*-tolylsulpho-*m*-phenylene diamine $C_6H_4(NH.SO_2.C_6H_4.CH_3)_2$ forms 1,3-di-*p*-tolylsulphamino-6-nitrobenzene, $C_6H_3(NO_2)(NH.SO_2.C_6H_4.CH_3)_2$, and diphenylsulpho-*m*-tolylene-diamine $C_6H_5(CH_3)(NH.SO_2.C_6H_5)_2$ [$CH_3:(NH.SO_2.C_6H_5)_2 = 4:1:3$] forms 1,3-diphenylsulphamino-4-methyl-6-nitrobenzene. The substance may be treated with the dilute nitric acid, or in suspension dissolved in a suitable solvent such as alcohol or benzene. The nitro derivatives produced as described above are converted into the corresponding nitrochammes by the action of concentrated sulphuric acid. By the action of reducing agents the corresponding amino derivative of the diarylsulpho-*m*-chamme is produced. The following example illustrates the invention: 41.4 parts by weight of di-*p*-tolylsulpho-*m*-phenylenechamme are dissolved in 120 parts by weight of alcohol; 40 parts by weight of dilute nitric acid of sp. gr. 1.2 are added, and the mixture is boiled under a reflux condenser for 15 hours. The nitro derivative separates on cooling, and is filtered off, washed and dried. It melts at 169° C. To eliminate the two *p*-tolylsulphamino groups from this nitro compound, 1 part by weight of the compound may be introduced into 3 parts by weight of concentrated sulphuric acid with stirring and heating to 30–40° C. When the nitro compound is completely dissolved, the mass is poured into ice, the solution neutralised with sodium hydroxide or carbonate, and the 1,3-diamino-6-nitrobenzene filtered off, washed and dried. Again, for example, 42.8 parts by weight of di-*p*-tolylsulpho-*m*-tolylenechamme [$CH_3:(NH.SO_2.C_6H_4.CH_3)_2 = 1:2:4$] are mixed with 160 parts by weight of water and 40 parts by weight of dilute nitric acid of sp. gr. 1.2. This mixture is heated on a steam-bath for about 10 hours, with stirring. The parent material, which is a light powder, and floats on the liquid, gradually changes to the nitro compound and subsides in the form of deep yellow grains. The product is filtered off, washed and dried. After recrystallisation from glacial acetic acid, it melts at 210° C.—E. F.

p-Imidophenylthiarsulphonic Acid; *Manufacture of a New — and of a Colouring Matter [Azo Dyestuff] therefrom.* C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 9325, May 3, 1905.

A new sulphonic acid of *p*-aminophenylether is obtained by heating the acid sulphate of the ether; 186 parts of the ether are suspended in a small quantity of water, and 100 parts of sulphuric acid are added. The mass is dried at 100° C., and then heated to 180° C. for twelve hours; the product is dissolved in hot sodium carbonate solution, filtered and precipitated by the addition of acid. When diazotised and combined with β -naphthol, this substance gives a new azo dyestuff, the metallic salts of which form red lakes of technical value.—T. F. B.

Indigo-White [Indigo Dyestuffs]; Manufacture of Solid Stable Alkali Salts of —. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 23,122, Nov. 10, 1905.

Dry alkali salts of indigo-white, stable in the air, are obtained by evaporating aqueous solutions of these substances *in vacuo*, preferably in thin layers. Better results are obtained with the monosodium salt, or a mixture of the mono- and di-sodium salts, than with the latter only. The solutions obtained by reducing indigo with finely divided iron in presence of alkali hydroxide are very suitable for the purpose, as they contain no other salts and no excess of alkali. For example, 50 parts of pure Indigo (B.A.S.F.) in powder are reduced with 25 parts of iron-powder, 12 parts of sodium hydroxide and 64 parts of water. The liquid is filtered from iron mud and evaporated *in vacuo* at 80°–90° C. until no more water

comes off. On cooling, a brittle product is obtained which, in thin layers, is transparent and has a red colour. It is easily soluble in water.—E. F.

UNITED STATES PATENTS.

Sulpho-Acid and Process of Making same. G. Kalischer, Frankfort-on-the-Maine, Germany. Assignor to Cassella Colour Co., New York. U.S. Pat. 807,117, Dec. 12, 1905.

New sulphonic acids of the general formula,

where X represents an aromatic radical, are obtained by condensing in aqueous solution 1 mc. of 1,2-diamino-naphthalene-5-hydroxy-7-sulphonic acid with 2 mols. of an aromatic aldehyde. The products are powders of a slightly yellowish colour, insoluble in water, soluble in alkalis, and precipitated from their alkaline solutions by the addition of acids.—E. F.

Dye [Azo Dyestuff]; Red Azo — and Process of Making same. F. Klugeemann and G. Kalischer, Frankfort-on-the-Maine, Germany. Assignors to Cassella Colour Co., New York. U.S. Pat. 807,119, Dec. 12, 1905.

Disazo dyestuffs are prepared by condensing in aqueous solution 1 mol. of 1,2-diaminonaphthalene-6-hydroxy-7-sulphonic acid with 2 mols. of a monoazo dyestuff, or with 1 mol. each of two different monoazo dyestuffs, containing an aldehyde group. The monoazo dyestuffs in question are prepared by combining 1 mol. of diazotised *m*-amino-benzaldehyde with 1 mol. of a naphthol sulphonic acid. Tisazo dyestuffs, which dye un mordanted cotton in red shades, are obtained by combining an aromatic diazo compound with 1 mol. of a disazo dyestuff, prepared as described above from 1,2-diaminonaphthalene-6-hydroxy-7-sulphonic acid, and 2 mols. of a monoazo dyestuff containing an aldehyde group.—E. F.

Dye [Azo Dyestuff]; Zinc Azonaphthol — and Process of making same. K. Elbel, Assignor to The Firm of Kalle and Co., Akt.-Ges., Biebrich, Germany. U.S. Pat. 807,322, Dec. 12, 1905.

Zinc compounds of 2-hydroxynaphthalenesulphonic-acid-1-azo- β -naphthols are obtained by treating 1-amino-2-naphtholsulphonic acids in concentrated aqueous solution or suspension with alkali nitrite and, at least, an equivalent amount of zinc sulphate, and bringing the product so obtained into reaction with a concentrated alkaline solution of β -naphthol. The products dye wool from an acid bath in bluish-red to violet shades, which are turned into bluish-black by subsequent treatment with a bichromate. The zinc compound of 2-hydroxynaphthalene-4-sulphonic-acid-1-azo- β -naphthol, obtained in the manner described above from 1-amino-2-naphthol-4-sulphonic acid, is specially claimed. (See also Fr. Pat. 353,780 of 1905; this J., 1905, 1062.)—E. F.

Indigo; Process of Brominating —. A. Schmidt, Assignor to Farbwerke vorm. Meister, Lucius und Brünning, Höchst-on-the-Maine, Germany. U.S. Pat. 807,782, Dec. 19, 1905.

Anthracene Derivatives [Anthracene Dyestuffs]; Production of New — Soc. Badische Anilin und Soda Fabrik. Fr. Pat. 357,138, Aug. 23, 1905. Under Int. Conv., Jan. 3 and April 3, 1905.

A DIANTHRAQUINONYLAMINE of the formula

is obtained in perfectly pure crystals by the action of 1-aminoanthraquinone on 2-chloroanthraquinone in presence of a condensing agent, such as copper acetate, sodium acetate together with cuprous chloride, &c., and of a diluent such as naphthalene or nitrobenzene. The same substance may be obtained, though less easily, by the action of 2-aminoanthraquinone on 1-chloroanthraquinone. For example, a mixture of 2.4 kilos of 2-chloroanthraquinone, 2.7 kilos of 1-aminoanthraquinone, 100 kilos of naphthalene, 2.5 kilos of anhydrous sodium acetate and 0.5 kilo. of cuprous chloride is boiled for 15 hours. By extracting the naphthalene with boiling toluene, dianthraquinonylamine is obtained in small crystals with metallic lustre. It may be transformed into dyestuffs in many ways. With fuming sulphuric acid at 100°–130° C. in presence of boric acid, it is converted into a dyestuff which dyes wool in brownish-red shades. In an analogous manner 1-halogenoanthraquinones may be condensed with 1-aminoanthraquinone. Dihalogeno- and diaminoanthraquinones may be employed in the same way and also derivatives of any of these substances. In the case of the condensation of 1-amino-4-halogenoanthraquinone or their derivatives with 1-aminoanthraquinone, it is advisable, in order to avoid secondary reactions, to employ the former in the form of their acetyl derivatives. The acetylanthraquinonylamines thus obtained are readily hydrolysed, forming the corresponding amino compounds. These substances, also, are readily converted into dyestuffs; after saponification they give blue shades on wool, which are said to be perfectly fast. For example, a mixture of 1500 kilos. of nitrobenzene, 100 kilos. of 1-acetamino-2-methyl-4-chloroanthraquinone, 140 kilos. of 1-amino-2-methylanthraquinone, 100 kilos. of anhydrous sodium acetate, and 20 kilos. of cuprous chloride are boiled for two hours. After cooling, the product is allowed to stand for some time, the solid filtered off and washed successively with nitrobenzene, alcohol, dilute hydrochloric acid and alcohol. It may then be crystallised from nitrobenzene. It is hydrolysed by dissolving in 10 kilos. of sulphuric acid of 66° B. and precipitating by the gradual addition of water. The mixture becomes hot and deposits the de-acetylated base on cooling. Derivatives of dianthraquinonylamine are also obtained from 4-halogeno-1-aminoanthraquinones, which are substituted in the *o*-position to the amino-group by treating them successively with nitrosulphuric acid and phenols, amines or derivatives of the same.

Other compounds of this nature such as 4,2-dihalogeno-1-aminoanthraquinone, also 1,5-diamino-2,1,6,8-tetrahalogenoanthraquinone and other compounds having two halogen atoms, each in *p*-position to an amino group, behave in an analogous manner. The products so obtained are readily sulphonated by fuming sulphuric acid in presence of boric acid. The sulphonic acids dye wool in very fast blue shades from an acid bath. For example, 10 kilos. of 4-chloro-1-amino-2-methylanthraquinone are dissolved in the cold in 100 kilos. of sulphuric acid of 66° B., and 12 kilos. of nitrosulphuric acid, containing 20–21 per cent. of nitric acid, are added without allowing the temperature to rise. The mass acquires an intense brownish-red colour. It is stirred for an hour or two and 10–15 kilos. of phenol are then added. The colour changes to bright blue. After stirring for 2–3 hours the product is poured into water and the precipitate filtered off, washed and dried. It crystallises from naphthalene in bright blue crystals, insoluble in alkalis. The anthraquinone derivatives described above are sulphonated as follows:—10 kilos. of the blue substance are stirred into a mixture of 190–200 kilos. of fuming sulphuric acid (containing, for example, 45 per cent. of sulphur trioxide) and 10 kilos. of dry boric acid. The whole is then heated to 100°–120° C. It is then poured into water, filtered and washed with a dilute salt solution.

The dyestuff is preferably used as a paste. The shades obtained on both mordanted and unmordanted wool are blue and very full.—E. F.

Anthracene Derivatives [Anthracene Dyestuffs]; Production of New — Soc. Badische Anilin und Soda Fabrik. Fr. Pat. 357,219, Aug. 25, 1905.

DERIVATIVES of dianthraquinonyls,

are obtained, either by the action of copper powder or of other dehalogenising metals on iodo-anthraquinones, or by condensing diazo compounds from amino-anthraquinones in such a manner as to eliminate the nitrogen of these compounds. The latter reaction is effected particularly easily by condensing the diazo-sulphates in presence of acetic anhydride, together with certain metals, such as copper powder. For example, 10 kilos. of 1-chloro-2-methylanthraquinone are mixed with 8 kilos. of copper powder and heated to about 260° C. The temperature of the molten mass soon reaches 280°–290° C., yellowish vapours being evolved. After 20–30 minutes the temperature begins to fall. The mass is then heated to about 280° C. for a quarter of an hour, allowed to cool, powdered, and the copper removed by solution in dilute nitric acid. The remaining mass is washed with water, dried, and the 2,2'-dimethyl-1,1'-dianthraquinonyl extracted in a state of purity by means of boiling xylene. Again, for example, 20 kilos. of 1-amino-2-methylanthraquinone are dissolved in 250 kilos. of sulphuric acid of 66° B., 8 kilos. of sodium nitrite are then gradually added with stirring, and without rise of temperature. When diazotisation is complete, the mass is poured on to ice, allowed to stand for three hours, filtered and the solid diazo-sulphate washed with a very little cold water, then with alcohol, and, if necessary, with a little ether. 10 kilos. of the air-dried 2-methylanthraquinone-1-diazo-sulphate so obtained are mixed with 60 kilos. of acetic anhydride, and 2 kilos. of copper powder are then added. The temperature of the mass gradually rises, nitrogen is evolved, the solution becomes violet in colour, and deposits a pale yellow precipitate after some hours. It is heated for a short time in a water-bath, the acetic anhydride decomposed with hot water, and the unattacked copper removed by means of hot dilute nitric acid. The 2,2'-dimethyl-1,1'-dianthraquinonyl is then filtered off and washed with hot water. These new anthracene derivatives can be converted into dyestuffs. If 2,2'-dimethyl-1,1'-dianthraquinonyl or its derivatives are heated by themselves, or treated with dehydrating agents, they lose 2 mols. of water, forming dyestuffs which are converted by alkaline reducing agents, more particularly by hydrosulphites into vats which have the red colour of rhodamine. These dyestuffs have the probable formula

These vats dye cotton in red shades, changing on washing to orange or yellow shades, which are very bright and absolutely fast. The dyestuffs may be printed, with or without a reducing agent, in presence of alkali, and then steamed. They may also be printed without either alkali or a reducing agent, and subsequently passed through an alkaline bath. For example, 1 kilo. of 2,2'-dimethyl-1,1'-dianthraquinonyl, 15 kilos. of potassium hydroxide and 5 kilos. of methyl alcohol are heated to 165°–170° C. under a reflux condenser for one to two hours. The melt is then treated with water, in which it dissolves to a crimson solution. A current of air is passed through the boiling solution until the precipitate acquires a distinctly brown colour. The whole is then acidulated slightly and the precipitate filtered off and washed. Again, for example, 2,2'-dimethyl-1,1'-dianthraquinonyl is

heated to 350°–380° C., whilst stirring well. The melt is greenish-brown in colour and becomes reddish-brown after some time. After half an hour it is allowed to cool and the hardened mass is dissolved in 10–15 times its initial weight of sulphuric acid of 66° B. The product is precipitated by means of ice and water, and is washed with water. It is insoluble in water, and in dilute alkalis and acids.—E. F.

(Continued from Page 47.)

Solution and Pseudo-Solution. 11*. [Theory of Dyeing] E. Linder and H. Piéron. Chem. Soc. Trans., 1905, 87, 1906–1936.

This paper continues the study of solution and pseudo-solution originated by the authors in 1892 (this J., 1892, 64; likewise Chem. Soc. Trans., 1895, 67, 63; 1897, 71, 568); (also Dreaper, 1904, 95; and 1905, 223). The present paper is arranged in three sections.

I. *Physical and Chemical Properties of Colloidal Arsenious Sulphide.*—The authors continue their investigation into the nature of the precipitate that separates when colloidal arsenious sulphide is coagulated by metallic salts. They regard such coagula as metallic derivatives of a complex hydrosulphide formed by interchange of hydrogen for metal. Thus,

The coagulation process for salts of un-, bi-, and tri-valent metals is reviewed in the light of this hypothesis. Tetravalent metals, for example, platinum and zirconium, are found to be non-coagulants of arsenious sulphide in dilute solution. The aggregation and de-aggregation phenomena of arsenious sulphide have been studied microscopically.

II. *Physical and Chemical Properties of Colloidal Ferric Hydroxide.*—The authors discuss the properties of ferric hydroxide. Various grades of the colloidal hydroxide have been prepared by dialysis: The lowest, with aggregates visible under the microscope (1/10th Obj.), the highest diffusible and filterable, but showing a polarised beam in Tyndall's experiment. The physical and chemical properties of the higher grade solutions, and the coagulation phenomena of the colloidal hydroxychloride, have been studied by methods similar to those applied in the investigation on arsenious sulphide.

III. *Dyeing a Phase of Coagulation.*—The authors show that when a solution of "ferric hydroxide" (hydroxy chloride) is just coagulated by a dilute solution of ammonium sulphate, the whole of the iron and sulphuric acid separate as an insoluble hydroxysulphate, whilst an equivalent amount of ammonium chloride remains in solution. If in place of ammonium sulphate a solution of "Soluble Blue," or Nicholson's Blue be taken, the result is precisely similar. At a certain critical point, a red coagulum separates which contains the whole of the iron and the whole of the sulphuric acid added, an equivalent amount of sodium chloride remaining in solution. The coagulative power of "Soluble Blue," calculated from the amount used to exactly coagulate a given volume of hydroxide, is 200, precisely the value obtained for sodium sulphate; Nicholson's Blue gave a much higher figure. If the coagula be extracted exhaustively with strong alcohol to remove every trace of adherent dye, foxy-red precipitates remain. On digesting these extracted coagula with dilute sulphuric acid or concentrated salt solutions, a deep blue solution is obtained*—the hydroxy-dye sulphate is decomposed, yielding the free sulphuric acid or corresponding sulphonate. If in place of the acidic dye, Aniline Blue, an

"equivalent" solution of a basic dye, Methyl Violet, be used, no coagulation results. The latter dye is a chloride, and chlorides coagulate ferric hydroxide only in highly concentrated solution. With arsenious sulphide, the behaviour of the dyes is reversed—Methyl Violet readily coagulates arsenious sulphide with formation of a dye-hydrosulphide derivative and liberation of hydrochloric acid, whilst Aniline Blue has no such power. Here the coagulating agent is the chloride of a basic dye, viz., Methyl Violet, which acts like aluminium chloride; whilst the sodium salt of an acidic dye, like other sodium salts, only coagulates arsenious sulphide in highly concentrated solution. Similar results are obtained with Hofmann's Violet and with Magenta.

The authors consider that these facts indicate that the coagulation phenomena of such dyes are precisely analogous to those of metallic salts.

If the addition of ammonium sulphate to a solution of ferric hydroxide be continued beyond the point at which the coagulum separates, the excess remains in solution. With Aniline Blue, this is not the case; the coagulum that separates continues to take up dye with avidity, withdrawing from solution in this way an amount four to five times as great as that required to coagulate the hydroxide before the excess of dye added begins to colour the liquid. Up to this point, the supernatant liquid remains clear and colourless; no trace of alkali can be detected. The dye is therefore taken up as a whole, not as a sulphonic acid. Similar results are obtained if Methyl Violet be added to arsenious sulphide. In both cases the coagula may be said to have been "dyed." Excess of Aniline Blue is also taken up by ferric hydroxide coagula in general, and Methyl Violet by arsenious sulphide coagula.

On the other hand, if ferric hydroxide coagula are treated with Methyl Violet, or arsenious sulphide coagula with Aniline Blue, no appreciable amount of the dyes is taken up. Ferric hydroxide has a selective affinity for the acidic dye, arsenious sulphide for the basic dye. With respect to the cause of this difference, the authors sought for a physical rather than a chemical explanation of the mutual attraction of dye and coagulum, since in the present simple cases of "substantive" dyeing they have shown that in the first, or "coagulation," stage of the process, chemical reactions occur which practically exhaust themselves before the second, or "colour absorption," stage commences, and that there is evidence that the dye taken up during the latter operation is absorbed as a whole. Witt's theory of solid solution, they consider, affords no adequate explanation of the phenomena, as the dyes up to a certain point are completely withdrawn, leaving the solution colourless and neutral. During the present year Dreaper (this J., 1905, 24, 223) has sought to connect the phenomena of the dyeing process with the de-solution phenomena of colloids. He holds, with Krafft, that the process of dyeing in the great majority of cases consists in the separation of colloidal salts on or in the fibre. The colloid molecules, he argues, are in a state of unstable equilibrium. Under the influence of a "porous fibre substance" aggregation occurs to such an extent that they are thrown out of solution on the fibre and adhere to it by mutual attraction. The authors endeavour to advance beyond the position taken up by Dreaper. They seek to explain why a "porous fibre substance"—ferric hydroxide—should absorb and retain Aniline Blue and reject Methyl Violet, whilst another "porous fibre substance" of a similar physical structure—arsenious sulphide—rejects the first and absorbs the second. They believe an answer is to be found by comparing the physical properties of the four solutions. The more important properties are summarised as follows:—

All four solutions are aggregated and finally coagulated by sodium chloride, forming granular hydrogels. All contain molecular aggregates too small to be visible under high powers of the microscope. All exhibit electrical properties which indicate that a difference of potential exists between the molecular aggregates and the fluid (Quincke), in other words, the aggregates carry an electric charge: the two "basic" compounds, Methyl Violet and ferric hydroxide, a *plus* charge; the two "acidic" compounds, Aniline Blue and arsenious sulphide, a

* The experiment is best performed by placing a small quantity of the extracted coagulum on a piece of dry filter paper. If the coagulum is then moistened with the acid or salt, a deep blue ring is formed. The coagulum must not be boiled in contact with glass, the extracted alkali decolorises it.

minus charge. Any two oppositely-charged hydrosols in dilute aqueous solution combine to form a pseudo-solution the compound aggregates of which possess electric properties which depend on the relative proportions of the constituents present. Thus:

Excess of Methyl Violet (+) with Aniline Blue (—) is electro-positive;

Excess of Aniline Blue (—) with Methyl Violet (+) is electro-negative;

Excess of ferric hydroxide (+) with arsenious sulphide (—) is electro-positive;

Excess of Aniline Blue (—) with ferric hydroxide (+) is electro-negative;

and so on.

Any two oppositely-charged hydrosols in strong aqueous solution are mutual coagulants. Thus

Methyl Violet (+) aggregates and finally coagulates Aniline Blue (—).

Ferric hydroxide (+) aggregates and finally coagulates arsenious sulphide (—)*.

Further, the hydrosols which separate when ferric hydroxide and arsenious sulphide are coagulated by metallic salts, still retain the same selective affinity for the dyes which will flocculate them—the hydrosol of ferric hydroxide for Aniline Blue, that of arsenious sulphide for Methyl Violet. The authors regard this fact as evidence that the granular aggregates in these hydrosols still retain some charge. In other words, the difference of potential existing between the molecular aggregates and the fluid in the hydrosol state is not destroyed by coagulants, but only reduced to a point at which the forces of cohesion are just able to overpower the forces of repulsion brought into play by such difference of potential.

In conclusion, they regard the simple processes of "substantive" dyeing described above as taking place in two stages:—

Stage 1.—The "coagulation stage," in which simple ionic interchange takes place between the "fibre substance" (colloid) and the dye, resulting in the separation of insoluble dye derivatives retaining a feeble charge.

Stage 2.—The "colour absorption stage" in which the coagula produced in Stage 1 attract and retain (as a whole) the oppositely-charged particles of the dye substance.

p-Phenylenediamine and Quinonediamine: Injurious Effects of — on the Health of Workpeople. E. Edmann and E. Vahlen. Arch. exp. Pathol. u. Pharmac. 53, 401—418. Chem. Centr., 1905, 2, 1809—1810.

p-PHENYLENEDIAMINE is used in the dyeing of furs, and especially for colouring hair brown or black. Workpeople engaged in the manufacture of this compound are said to suffer various injurious effects, and the authors attribute these to the diamine itself and to its oxidation products, especially quinonediamine, $\text{NH} : \text{C}_6\text{H}_4 : \text{NH}$. This latter compound is very unstable and readily polymerises to a dark brown colouring matter ($\text{C}_{12}\text{H}_{10}\text{N}_2$). The authors are of the opinion that the use of *p*-phenylenediamine as a dye for human hair should be forbidden. —A. S.

Yarns; Manufacture of Coloured Polished —. W. H. Duckworth, Sale, Cheshire. Eng. Pat. 6,230, March 24, 1905.

THE ordinary method of production of polished coloured yarns from cotton or other vegetable fibres consists in first

* In this case, some slight chemical action is noticed: the filtrate contains traces of ferrous chloride, due, doubtless, to reduction of the hydroxychloride present.

mordanting or preparing the bleached or "boiled off" yarn, then dyeing (or immediately dyeing with direct colours), then sizing and finally polishing on brushing machines. This process is lengthy, and, according to the present patent, the polishing size, mordants, assistants, solvents and dyestuffs or pigments employed are all mixed and directly applied to the bleached or "boiled off" yarns. A polishing size is first made by boiling in water animal, vegetable or mineral fats or waxes, together with one or more of the following substances:—Farina, starches, dextrin, sago flour, tapioca flour, arrowroot, cereals, gums, sugars, soap, shellac or animal and vegetable gelatinous materials. To this prepared size are then added either dyestuffs, coloured pigments or lakes, with or without the addition of china clay, assistants, solvents and mordants. The bleached or "boiled off" yarns are impregnated with this size mixture in the usual way, steamed, allowed to stand for several hours and then polished on brushing machines as usual. Oxidising, reducing, alkaline or acid vapours or gases, such as chlorine, formaldehyde, acetic acid, ammonia, &c., may be introduced in the steaming process. For example, a black polished yarn is produced as follows:—The bleached or "boiled off" yarn is wrung out and worked for a few minutes in the slightly warm or cold size made by boiling together in water 5 parts of white paraffin wax, 5 parts of brown paraffin wax and 12 parts of china clay. This is allowed to cool somewhat and a mixture of 18 parts of farina, 18 parts of sago flour, and 150 parts of water is added and well boiled, with stirring, until a stiff paste is produced. To every 135 parts of size, 45 parts of Fast Steam Black (a commercial logwood preparation), 45 parts of chromium acetate solution of 3% T., and about 135 parts of water are added. The shade of black is varied by the addition of such dyestuffs as Auramine, extract of Persim berries, &c., to this size. The yarn is then allowed to stand in a cool place to absorb the dyestuffs and size, the excess being drained off in a few hours, and is then steamed at the atmospheric pressure, or a pressure slightly higher. When the colour is thoroughly developed by the steam, which usually takes about 30 minutes, the yarn is removed from the steamer, allowed to cool and polished as usual. Black polished yarns may also be made in which the Fast Steam Black is replaced by "carbon black powder." Coloured shades of polished yarn are produced by dissolving a direct cotton dyestuff in water and adding it, together with about five times its weight of sodium phosphate or other suitable assistant, to a size made as in the first example, omitting the mordant. In all cases the yarn polishing size contains paraffin wax or similar substances of a fatty or waxy nature, which, being boiled with water and starchy matter form an emulsion. This separates after being applied to the yarn and allows the water to be squeezed out, so that the yarn takes a polish on being brushed, no heat being required for this purpose. —E. F.

Waterproofing of Soft Felt Hats. J. P. L. Maurel, Albi, France. Eng. Pat. 16,726, Aug. 17, 1905. Under Int. Conv., March 8, 1905.

ONE kilo. of alum is dissolved in 2 litres of boiling water and 1.7 kilo. of lead acetate in 3 litres of boiling water. The two solutions are mixed while warm and the liquid decanted from the resulting precipitate. After the hats have been dyed and dried, they are placed in a bath made by mixing 1 litre of the decanted liquid obtained as described above with 12 litres of water. They are then removed and dried in the open air or in a stove. The length of time during which the hats are immersed in the liquid varies with the thickness and nature of the felt. For hair felt about 8—10 hours and for merino felt about 2—3 hours are necessary.—E. F.

UNITED STATES PATENTS.

Mordant; Lactic —. A. A. Chaffin, Littleton, Mass. U.S. Pat. 807,019, Dec. 12, 1905.

AN "assistant mordant" of lactic acid and an ammonium.

salt is claimed, the lactic acid being in excess of the acid combined in the form of ammonium salt.—T. F. B.

Dyeing; Apparatus for — J. A. Willard, Assignor to The Vacuum Dyeing Machine Co., Chattanooga, Tenn. U.S. Pat. 796,381, Aug. 1, 1905.

The apparatus which forms the subject of this invention, comprises an outer receptacle 1 (see Fig.), to the bottom of which is secured an inner, annular casing 4, tapering downwards, leaving a space 4b between the receptacle and casing; a removable, perforated bottom-plate 6, adapted to support within the casing the materials to be dyed; a compression-plate 7, capable of being raised or lowered by means of chains attached to a pulley 8, carried by a trolley 9, upon a trolley-line 10; vertical rods, provided with stop-plates, just above 1, serving to hold the plate 7 in position within the casing 4; pipes 17, 18, 23, 29, 30, 32; a pump 28; couplings, valves, a steam-pipe, &c. The arrangement is such that the central, vertical rod employed in dyeing apparatus (see U.S. Pat. 755,422; this J., 1904, 439) of a nature similar to the apparatus now claimed is dispensed with.

The operation of the apparatus is as follows:—The

Dyeing-Machine; Duplex — J. A. Willard, Assignor to The Vacuum Dyeing Machine Co., Chattanooga, Tenn. U.S. Pat. 796,382, Aug. 1, 1905.

Two dye-vessels, with inner casings, material-supporting plates, liquor- and steam-pipes, &c., constructed and arranged as described in U.S. Pat. 796,381 (see preceding abstract), are placed at a convenient distance apart, so that the same pump, material-compression plate, pulley-hoist and trolley rail may serve for both vessels. The object of the invention is to enable the output of dyed textile materials to be doubled without duplicating the whole of the apparatus, the materials in one of the vessels being dyed and afterwards washed, while those in the other vessel are being removed and replaced by undyed materials.—E. B.

Dyeing Machine. J. A. Willard, Assignor to the Vacuum Dyeing Machine Co., Chattanooga, Tenn. U.S. Pat. 796,383, Aug. 1, 1905.

A DYE-VESSEL 1 (see Figs. next page), mounted upon a suitable support, is connected, by means of a system of pipes, with a pump 33 (Fig. 1). Two removable, perforated plates, 16

materials (loose wool, &c.) to be dyed are conveyed upon the plate 6 into the casing 4 and there compressed by the plate 7. The dye-liquor to be employed is run into the receptacle in quantity sufficient to keep the plate 7 submerged during the dyeing operation. Steam is admitted into the pipe 12 to heat the dye-liquor, which is drawn, by the action of the pump, from the space 4b, through pipes 23 and 29, and by the same means caused to return through pipes 30, 32, 18 and 17 to the bottom of the receptacle 1. The liquor then passes upwards through the plate 6, the textile materials, and the plate 7, to the space 4b whence it is again drawn. After circulating in this manner for a few minutes, the valves are reversed and the dye-liquor is made to flow in the opposite direction. Finally, after being circulated in both directions as often as is necessary, the dye-liquor is withdrawn and the dyed materials are washed with water before being removed from the apparatus.—E. B.

and 11, which, when in use, are placed respectively at the top and bottom of the vessel, serve to compress, during the dyeing operation, the textile materials to be dyed, while allowing dye-liquors to flow through them. These are kept in position by vertical rods, 2, 3, 4, 5 and 6, secured to the bottom of the vessel, a reinforcing plate 16 carrying four or five tapering collars 18, through which the rods pass, being secured above the upper plate. A chamber 22, into or from which the dye-liquor passes from or into the vessel through an opening in its side, contains a filter 23. Rings 13 are fixed in the plates to enable them to be moved into and out of the vessel. The materials are placed upon and removed from the plate 11 while this is outside the dye vessel. The dyeing is accomplished by filling the vessel with the required dye-liquor and circulating this alternately in opposite directions, heating it by means of a steam-pipe, 47, while the materials are compressed, sufficient dye-liquor being employed to

FRENCH PATENTS.

Viscose: Process for Making Threads and Films of —
S. Pissarev. Fr. Pat. 357,056, Aug. 19, 1905.

SOLUTIONS of salts of organic bases, such as aniline, pyridine or naphthylamine are employed to render viscose threads or films insoluble. These bases are stated to be very easily removed by washing. The process is stated to be of value when it is desired to colour the products, e.g., when aniline has been employed, the product may be treated with a solution of a chlorate and hydrochloric acid, and then steamed and dried, thus producing Aniline Black.—T. F. B.

Cellulose Solutions: Process of Making — by means of Alkylamines. E. W. Friedrich. Fr. Pat. 357,171, Aug. 24, 1905. XIX., page 88.

Threads: Apparatus for Making Artificial — E. W. Friedrich. Fr. Pat. 357,172, Aug. 24, 1905. Under Int. Conv., Sept. 7, 1904.

THE apparatus consists, as shown in the accompanying figure, of a tube *a*, through which the cellulose or other solution flows, and which communicates with a number of forming orifices *b b*; also a tube *d* by which the coagulating or hardening solution is introduced. The threads thus formed are carried up the tube *c*, in the interior of the upper part of which (*c*) is a helical groove, which causes the liquid to rotate, thus twisting the several threads together into one thread. This passes out of the apparatus, over the pulley *h*, from which it is fed on to an endless band of fabric, around which it makes a complete circuit; during its passage it passes between squeezing rollers, one of which actuates the endless band, and is finally wound on a bobbin. The coagulating or harden-

FIG. 2.

submerge the materials during the operation and so prevent them from coming into contact with the air "before the colour has been set."—E. B.

Dyeing Apparatus. G. A. Friedrichs, Assignor to C. A. Proulx, Woonsocket, R.I. U.S. Pat. 806,793, Dec. 12, 1905.

THE apparatus comprises a dye vat A containing a basket C with perforated walls for holding the rovings, &c., to be dyed, a perforated spray-pipe B for the introduction of dye-liquor, a pipe F for withdrawing dye-liquor from

ing solution passes up into trough *f*, and overflows through pipe *g*.—T. F. B.

Silk Works, &c.; Process for the Recovery of the Alcohol and Ether contained in the Air of Artificial — J. M. E. Dervin. Fr. Pat. 350,298, Nov. 8, 1904.

The air is passed in succession through two batteries of absorption towers or columns fed with concentrated sulphuric acid, and cooled by water so that the temperature does not rise above 18°–20° C. In the first series of towers, the ether, alcohol and moisture are all absorbed at first, but as the acid becomes diluted by absorbed moisture, its power of absorbing ether diminishes, and finally only the water and alcohol are retained, the ether passing on to be absorbed in the second series of towers. When the acid in the second series of towers is saturated, it is distilled *in vacuo* for recovery of the ether and then used over again. After being used several times in this way for the absorption of ether, the acid contains a certain quantity of ethylsulphuric acid; it is now transferred to the first series of towers, and used for the absorption of alcohol and moisture, the alcohol being subsequently recovered by known methods.—A. S.

Silk, Artificial; Recovery of Solvents, especially Alcohol and Ether, from Bobbins of — J. Douge. Fr. Pat. 350,835, April 21, 1905.

In the manufacture of artificial silk by the Chardonnet process, considerable quantities of alcohol and a small quantity of ether are retained by the filament, and are afterwards lost by evaporation. The recovery of these substances, by evaporation under reduced pressure, is

said by the patentee to be unsatisfactory as the apparatus is complicated, the operation delicate and dangerous, and the fibre undergoes deterioration in properties. According to the present invention the alcohol and ether are removed from the fibre by systematic extraction with water by diffusion, in much the same manner as in the extraction of sugar from beets, the filaments, highly charged with solvents being treated with concentrated aqueous solutions of the same, and subsequently with more and more dilute solutions in succession until they are finally extracted by pure water. By using bobbins with longitudinal channels, to admit of free access of the liquid, and by exhausting systematically at 30°–35° C., a liquid containing 15–20 per cent. of alcohol may be obtained. By fractionating this liquid, 40–50 per cent. of the alcohol employed may be recovered. Other solvents of nitrocellulose, soluble in water, such as acetone, may be recovered in the same manner. The extracted fibre is said to be in an especially suitable condition for denaturation and other subsequent treatment. A form of apparatus for carrying out the extraction is described. —E. F.

Dyeing, Cleaning and Washing Leathers; Apparatus for — J. J. Brossard. First Addition, dated Aug. 21, 1905, to Fr. Pat. 354,530, May 22, 1905.

See Eng. Pat. 18,194 of 1904; this J., 1905, 1011.—T. F. B.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

(Continued from page 18.)

FRENCH PATENT.

Wallpapers; Printing — A. Fleury. Fr. Pat. 350,249, Oct. 22, 1904.

For printing wallpapers, &c., the inks hitherto employed have been made by mixing powdered pigments with glue, starch paste, gum or some other suitable adhesive. According to the present patent the adhesives hitherto used are replaced by a preparation of casein and borax. For example, technical casein is mixed with three to seven times its volume of water and technical borax is added (from 12 to 18 per cent. of the quantity of casein used); the whole is heated to a sufficiently high temperature to dissolve the borax and casein. A slightly pasty liquid is so obtained and is mixed with the pigments employed. After printing, the casein is rendered insoluble by means of formaldehyde; this is effected either by passing the printed paper through a solution of formaldehyde or by exposing it to formaldehyde vapour.—E. F.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

(Continued from page 19.)

Alkali Carbonates; Dissociation of — P. Lobeau. Ann. Chim. Phys., 1905, 6 [8], 422–432. Chem. Centr., 1905, 2, 1657 (See this J., 1903, 739; 1904, 60, 714).

According to Wittorf (Z. anorg. Chem., 1904, 39, 187; this J., 1904, 488), only the carbonates of lithium, sodium and potassium are dissociated between 800° and 900° C., whilst the carbonates of rubidium and caesium volatilise at that temperature. The carbon dioxide found by the author on heating the two last-named carbonates must have been, according to Wittorf, derived from the action of the volatilised carbonates on the silicious glaze of the porcelain tube. The author has repeated the experiments, and finds that of the five alkali carbonates above mentioned, caesium carbonate is the only one that is appreciably volatile, and further that the dissociation of caesium carbonate is actual dissociation.

In the course of his experiments the author succeeded in crystallising the hydrate $8\text{CsCO}_3 \cdot 10\text{H}_2\text{O}$, from boiling concentrated alcohol.—A. S.

Vanadium; Use of Sodium Peroxide and of Hydrogen Peroxide for the Separation of ——, from Ores and Slags. M. M. J. Bouffort. Fr. Pat. 357,307, Aug. 2, 1905.

ORES and slags containing vanadium are treated cold with sodium peroxide dissolved in water, or by hydrogen peroxide solution. The vanadium is stated to pass into solution as vanadic acid or as vanadates, the purification of which may be effected by ordinary means.—E. S.

Barium Carbide and Metallic Manganese; Reduction of Barium Manganite in order to Obtain ——. C. M. J. Limb. First Addition, dated Aug. 22, 1905, to Fr. Pat. 304,720, Oct. 20, 1900. (Conquer. Eng. Pat. 7282, of Nov. 27, 1899; this J., 1901, 463.)

BARIUM manganite, mixed with carbon (not in excess) and a flux, such as chalk, barium carbonate or sulphate, or fluorspar, is heated, for instance, in an electric furnace, at a temperature too low for the formation of barium carbide. The metallic manganese thus produced is freed from the slag, which latter (containing the barium) is heated in another furnace with excess of carbon and an auxiliary oxide, preferably iron oxide, to the temperature necessary for the formation of barium carbide; the sulphur, phosphorus, silicon, &c., present, pass into the auxiliary metal. The barium carbide formed is treated with water for the production of barium hydroxide and acetylene.—E. S.

Clay; The Casting of ——. F. Foerster. Chem. Ind., 1905, 28, 733—740.

BESIDES the usual method of working a kneadable clay mass into the required shapes by hand, the process of casting has been employed, which consists in pouring a sufficiently fluid clay cream into plaster moulds, which, by absorbing a portion of the water from the fluid, allows a layer of clay to form on the walls of the moulds, and after a time the layer becomes sufficiently rigid to allow the still fluid portion of the clay cream to be poured off and the moulded object to be removed from the mould. During subsequent drying, however, such an object frequently cracks. This difficulty can be overcome, however, by making the water employed slightly alkaline, by the use of a 0.5 per cent. sodium carbonate solution, or 0.2 per cent. solution of sodium hydroxide, as the use of these diminishes the amount of water necessary to yield a thin fluid clay "slip." All clays do not yield these fluid "slips" with alkali, but many highly plastic stoneware clays possess this property and retain it when mixed with non-plastic and fluxing materials, such as quartz and felspar. The process is particularly applicable to bodies of complicated form, and is also cheap. In forming objects in plaster moulds, parts of the walls of which cannot be covered with clay "slip," the mould is inverted and the opening closed, while the liquid is introduced through a tube in the exit and allowed to rise slowly in the mould, while the air escapes through a separate tube. E. Weber has found that plastic clays mixed with burnt material retain the property of being cast and the process is therefore applicable, for instance, to the making of glass-house pots.

By long storage of ready mixed ceramic bodies the plasticity is improved, and, during this time, the water present in the body acquires an alkaline reaction, possibly due to its action upon the felspar. Consequently there appears to be a resemblance between this maturing process and the influence of small amounts of alkali upon certain clays. The author considers that the effect of alkalis upon clays is closely connected with the question of the nature of plasticity, and that clays do not differ essentially from colloidal substances. When a considerable amount of water is mixed with a highly plastic clay, the liquid

layers show no sign of clearing for perhaps two months, and a similar observation may be made with many colloidal solutions of gold, the particles being so fine that, to the human eye, they do not appear as separate bodies. Colloidal bodies are classed either as negative or positive, according as they tend to collect either at the anode or cathode under the influence of an electric current. The author has found that clays of very various kinds behave as negative colloids. Only a difference in the size of grain constitutes the distinction between colloids and fine particles in suspension, recognisable as such by the human eye. A turbid clayey fluid, containing negatively charged particles, follows the analogy of negative colloids, and is precipitated by acids, and maintained in a fluid condition by alkalis. On this theory, therefore, if the effect of the negative hydroxyl groups is to push the particles of clay apart, so that the water can glide more easily between them, then a smaller amount of water will produce the effect of rendering a given mass of clay "fluid" than would be required if the repellent effect of the hydroxyl groups were not present.

The fact that all clays do not admit of being cast is due to the want of the formation of colloidal conditions, owing to the presence of larger particles settling out from the liquid. The effect of small quantities of alkali is always greater on clays that contain a larger proportion of those fine particles that impress a colloidal character on the mixture. The fineness of the particles and their amount are shown by the time required for the clayey fluid to clear, and by the difficulty or ease with which the fluid can be filtered through paper. Those clays which remain turbid for a long time and cannot be filtered by the best papers, require the smaller amounts of alkali to enable them to be cast, while clays that clear easily on standing and are easily filtered, and do not stop the pores of the paper, do not become fluid for casting even with considerably larger additions of alkali. The alkali is said to have no effect upon the behaviour of the clay on burning, being present only in a relatively small proportion.

In the case of the alkali taken, the electrical effect of the negatively charged hydroxyl ions overcomes the attractive effect of the positive sodium ions, and the question arises as to the effect of other positive ions, e.g., calcium or barium. The author found that while 25 c.c. of N/20 caustic soda rendered 50 grms. of a certain clay quite "fluid," the similar quantity of N/20 calcium hydroxide or N/20 barium hydroxide left the clay quite stiff; and the fluid condition arose only when the lime water reached the same amount as required of distilled water. Partial replacement of the N/20 sodium hydroxide by the equivalent of lime water causes a diminution of the fluidity produced by 25 c.c. of solution on 50 grms. of the clay considered, when the lime constitutes more than one-fifth of the sodium hydroxide content. Nearly all clays, especially secondary clays, give up more or less calcium sulphate to water, and these amounts even when small have a prejudicial effect upon the fluidity. Hence the study of the aqueous extract of clays assumes increased importance, not only as regards the calcium salts, but other soluble components of the clay. A solution of ordinary sodium phosphate, to which a trace of sodium hydroxide has been added, acts in the same way on a clay in rendering it capable of being cast. It is noted with regard to calcium salts that objects formed in a plaster mould have so dense a structure that they will not take up a glaze when dipped. This may be due to the quite appreciable quantities of plaster absorbed from the mould, which produce a stiffening of those parts of the object in contact with the mould and on further drying and contraction of the object, the porosity necessary for absorbing the glaze is lost at these points.—W. & H.

Metallic Glazes on Enamels; Methods used by the Arabs to Produce —. L. Franchet. *Comptes rend.*, 1905, 141, 1237—1240.

The formulae used by the Arabs and their Italian successors are partly disclosed in MSS. in the British and South Kensington Museums; two are given below:—

	Arab.	Italian.
Copper sulphide	26-87	24-74
Silver sulphide	1-15	1-03
Mercury sulphide	—	24-74
Red ochre	71-08	49-49

These were ground with vinegar, and applied with the brush to the already baked enamel. The author finds that a great variety of iridescent and metallic tones can be obtained by one or the other or a mixture of the following formulae:—

	1.	2.	3.	4.	5.	6.
Copper carbonate ..	30	—	—	28	—	95
Copper oxalate	—	—	—	—	5	—
Copper sulphide	—	—	20	—	—	—
Silver carbonate ..	—	3	—	2	1	5
Diamuth subnitrate ..	—	12	—	—	10	—
Stannous oxide	—	—	25	—	—	—
Red ochre	70	85	55	70	84	—

Silver chloride and yellow ochre may be respectively substituted for silver carbonate and red ochre. The ingredients, ground with a little gum tragacanth and water, are applied with a brush to enamels melting about 990° C., and are fired at 650° C. in the reducing atmosphere already described (this J., 1906, 20). After cooling, the ferruginous deposit is rubbed off, and the colours thus brought out.

The author has thus imitated the old Arab wares, and has shown that sulphur, free or combined, is not necessary, that enamel has no action, that ochre may be dispensed with, that any organic gummy matter may be used instead of vinegar, and that bloom (*for. cit.*) is not needed in the furnace. The intensity and tone of the iridescence depend on the duration of the reduction, and the nature of the enamel. Enamels containing a colouring base—copper, iron, antimony, nickel—especially in presence of tin, give the best results.—J. T. D.

Manganese Dioxide; Determination of Traces of Iron in —. [for Glass Manufacture]. H. Cormimbœuf. XXIII., page 92.

FRENCH PATENT.

Glass in Tank Furnaces. Arrangement of Burner to allow of the Manufacture of White —. Société H. Boulan and Co. Fr. Pat. 557,270, Aug. 26, 1905.

This invention relates to a burner that will always yield an oxidising atmosphere in tank furnaces. In order to obtain a thorough intermixture of the gas and air, a series of pillars is arranged at the point where the gas enters the burner, and another series at the mouth of the burner, where it enters the tank.—W. C. H.

UNITED STATES PATENTS.

Wood; Apparatus for Forcing Fluids into —. S. Willner, Memphis, Tenn. U.S. Pat. 807,411, Dec. 12, 1905.

The log of wood is supported in a frame, one end of which consists of a number of grooves and ridges, and the other end of a screw device for forcing the log on to the ridges. The latter are sharpened so that they will enter the wood and the grooves are each connected with valve-controlled pipes for supplying liquid under pressure to the said grooves.—W. P. S.

Portland Cement; Method of Ageing —. W. O. Emery, Crawfordsville, Ind. U.S. Pat. 806,788, Dec. 12, 1905.

The method described for ageing Portland Cement consists in spraying the heated clinker with a dilute solution of a

carbonate or bicarbonate, such as ammonium bicarbonate, and afterwards exposing it to the action of gases containing a large percentage of carbon dioxide, for example, by introducing stack or kiln gases into the conveyor which carries the freshly-ground cement away from the grinding apparatus.—W. C. H.

FRENCH PATENT.

Wood; Process of Drying — by Preliminary Treatment of the Sap. Société Guignard et Lestande, Fr. Pat. 357,224, Aug. 16, 1905.

By this process freshly-sawn wood is placed in a stove, and subjected to the action of live steam, with the object of dissolving out the gummy and resinous substances, and removing them in the current of steam. The wood is afterwards dried in a drying chamber provided with a powerful fan, and heated with steam, which may be made to pass on to the stove above mentioned.—W. C. H.

X.—METALLURGY.

(Continued from page 27.)

Ore Flotation; Physics of — J. Swinburne and G. Rudolf, Proc. Faraday Soc., Dec., 1905 [Advance Proof].

THE flotation of ores (especially the Broken Hill sulphides), by which they are separated from gangue, is carried out by immersing them in dilute sulphuric acid or a strong solution of acid sodium sulphate at a temperature between 65° and 100° C. Bubbles of gas attach themselves to the sulphide particles and float them as a coherent scum to the surface, whilst the quartz and other gangue remains at the bottom. The gas is undoubtedly not hydrogen sulphide, but carbon dioxide, and the authors suppose it to be generated, not from calcite, but from carbonates produced by slight weathering of the ores. They assume that the attachment of the gas-bubbles to the particles is the result of equilibrium between two opposing forces—the adhesion between the particle and the liquid, which tends to wet the particle completely, to reduce the area of contact between bubble and particle, and ultimately to detach the bubble; and the surface tension of the liquid, which tends to include bubble and particle in one enclosing surface, to make that surface as small as possible, and hence to prevent separation of bubble from particle. While both forces are weakened by rise of temperature, adhesion falls off at much the more rapid rate, so that a high temperature is favourable to flotation. Adhesion is relatively much stronger in the case of the gangue than of the sulphides. The adhesion of liquids to solids, and hence the readiness or otherwise of solids to be wetted, is closely connected with the presence of an air-film surrounding them.

—J. T. D.

Metalliferous Sulphides; Concentration of — by Flotation. A. K. Huntington, Proc. Faraday Soc., Dec., 1905 [Advance Proof].

THE carbon dioxide which floats the sulphides in Broken Hill tailings (see previous abstract) is not due to calcite nor to carbonates produced by weathering of the ore, but to ferrous and manganese carbonates which exist in the ore, and are not decomposed by cold, but only by hot dilute acid. Ores which have been exhausted of these can be readily floated by adding these carbonates in their natural condition (siderite and rhodochrosite) to them and submitting the mixture to the hot acid treatment. The flotation is not due to electrostatic action, though, when carbon dioxide is generated in this way the escaping gas and the remaining liquid are oppositely charged. A certain blend between ore and gangue seems requisite, for certain blends very free from gangue, which cannot be floated if treated alone, are easily floated if previously mixed with sand, while the flotation of other ores which are easily separated in this way is injured by farther dilution with gangue. The air-film is not concerned; for ores which

have been thoroughly and completely wetted and denuded of any air-film can yet be floated perfectly. The author considers that the area of contact between a gas bubble and a solid depends on, and is inversely as the degree of wetting of the solid by the liquid concerned, the latter factor being measured by the angle between the solid and the liquid when the former is partially immersed. For a variety of sulphides this angle, in the case of water or weak acid, lies between 47° and 63°, while quartz and magnetite are completely wetted. The less the wetting the greater force is required to detach the bubble.—J. T. D.

Siemens-Martin Furnace; Treatment of Fluid Pig-Iron in the Basic — C. Dichmann, Stahl u. Eisen, 1905, 25, 1337—1346, and 1429—1437.

1. *Oxidising Action of the Furnace Gases.*—The ordinary Siemens-Martin process is an oxidising one. It would be reasonable to assume that the high temperature needed for its operation could only be attained by complete combustion and an oxidising flame, and calculations from the results of ordinary practice show this to be the case. The following example shows the way in which the author makes his calculations and gives data for similar ones:—Charge of 6500 kilos. of pig-iron and 13,120 kilos. of scrap; tests taken when melted, and four hours afterwards:—

	C	Si	P	Mn
Test at 4 a.m.	1.20	0.89	0.04	0.59
Test at 10 a.m.	0.00	0.00	0.01	0.25
Removed	1.11	0.89	0.03	0.34
Oxygen required, kilos.	201	196.6	7.6	19.4

Iron was also oxidised. The oxygen needed for this can be found if the quantity and composition of the slag are known, and the quantity of slag can be calculated from the silica in it. There went into the slag, silica from:—(1.) The metal, $196.8 \times 0.89 = 175.1$ kilos, of silica, or 374 kilos. of silica. (2.) The limestone, $11.48 \times 1.65 = 19$ kilos. (3.) The basic lining and the structure of the furnace (the former, calculated from the dolomite required (3.5 per cent. of the output of steel), and assumed to be regular over the time of the operation, amounted to 0.136 kilo. per minute, and the latter, taken similarly from the consumption of material for furnace repairs, to 0.123 kilo. per minute (the corresponding figures for the process with pig-iron and ore were 0.2 and 1.0 kilo. per minute respectively). The total silica from all these sources amounted in the four hours in question to 455 kilos.; and the percentages of silica and of iron in the slag being 28 and 9.23, the amount of oxygen combined with the iron as ferrous oxide was $455 \times \frac{9.23}{28} \times \frac{16}{56} = 43.5$ kilos. The total amount of oxygen provided by the furnace was therefore 558.1 kilos., or 2.33 kilos. per minute. Similar calculation for the 37 minutes to the end of the operation gave for that period 1.6 kilos. per minute. The calculated amount of slag was 1995 kilos., and that actually weighed was 1983 kilos. Similar calculations gave for the melting of a charge of 19,756 kilos. of pig-iron and 1638 of limestone, an oxygen supply of 0.65 kilo. per minute, and for the first 105 minutes of the working off of a charge of 19,705 kilos. of fluid pig-iron by exposure to the flame alone, an oxygen supply of 2.43 kilos. per minute.

2. *Oxidation by Iron Ore.*—It is usually assumed that in the working of the ordinary furnace, only a small proportion of the metal in the added ore is reduced and found in the metallic product, while with the Talbot process from 60 to 90 per cent. of it is thus recovered. The author gives details of the working of a charge of 1000 kilos. of limestone and 3276 kilos. of Krivo-Roger ore, containing 60.61 per cent., or 2182 kilos. of iron, on which were poured 20,300 kilos. of fluid pig-iron. After 190 minutes the reaction was over, and the slag (calculated as above) contained 318 kilos. of iron, so that 1864 kilos., or 85 per cent. of that contained in the ore, had gone into the bath. Further additions of 819 kilos. and 81 kilos. of ore were made, and the operation was finished in 110 minutes more,

after adding 100 kilos. of spiegel and 245 kilos. of ferro-manganese. The slag now only contained 294 kilos. of iron, so that the whole of the iron in the later additions of ore had gone into the bath; or 89 per cent. of the whole amount in the ore was reduced and recovered. The oxygen-consumption during the first 190 minutes was 1154 kilos. for the oxidation of the impurities removed from the metal (C 3.14, Si 0.79, P 0.12, Mn 1.57 per cent.), and 100 kilos. to oxidise the iron in the slag—total, 1254 kilos. The amount contained in the added ore was 933 kilos.; so that 321 kilos., or 1.69 kilos. per minute, were contributed by the furnace gases. The corresponding figure during the rest of the operation was 1.83 kilos. per minute. It appears, then, that no reduction of the ore can be effected by the furnace-gases themselves, the effect of which is to oxidise chiefly the iron, as the preponderating and most accessible constituent; and this in turn is reduced from the slag by the impurities in the pig-iron. The latter can only act, however, when the bath is completely fused; and the whole operation from beginning to end consists, in the author's view, of oxidation of the impurities by iron oxides in the slag, whether these iron oxides result from the solution in the slag of added ore or of oxide formed from the iron by the action of the furnace gases. This view is borne out by figures given by Harbord in 1886, in which the iron oxide in the slag rose to over 63 per cent. during the fusion of the pig-iron, and, after complete fusion, fell till the carbon was reduced to 0.07 per cent., when the slag contained 5.45 per cent. of iron, then rose slowly to the end of the operation when the normal figure of 9.88 per cent. of iron was reached.

3. *Reactions of Ferric Oxide with the Impurities of Pig-Iron.*—Lodebur first gave figures showing the amounts of iron reduced from ferric oxide by 1 kilo. of each of the impurities of pig-iron, and the heat-evolution accompanying the reaction, but he should have proceeded from ferric oxide or magnetic oxide, and he did not take account of the formation from silica and phosphoric anhydride of silicates and phosphates respectively. The author has recalculated these figures, and also the amount of heat needed to heat up the ferric oxide required in each case, on the assumptions that the fluid pig-iron is at 1250° C., and the ore at 0° C., and that the specific heat and latent heat of fusion of the ore are 0.19 and 60 respectively. The results are as follows:—

Substance, 1 kilo. of.	Heat evolved	Product.	Ferric Oxide needed.	Heat absorbed by Ferric Oxide	Nett heat result.
	Calories		Kilos.	Calories	Calories.
Silicon	+3630	Fe_2SiO_4	7.62	2191	+1439
	+3330	FeSiO_3	5.72	—	—
Manganese	+5026	Mn_2SiO_4	—	—	—
	+598	MnO	0.07	207	+220
Phosphorus	+878	$\text{Fe}_3(\text{PO}_4)_2$	6.88	—	—
	+1023	$\text{Fe}_2\text{P}_2\text{O}_7$	7.74	2225	-1202
Carbon	-3130	CO	4.44	1276	-4406

The figures are, of course, only rough approximations, but they show that the reactions of silicon and manganese are strongly exothermic, and that of carbon strongly endothermic, while that of phosphorus, exothermic in itself, yet lowers the temperature of the bath if the oxide required for it has to be heated up. In an experiment in which 16,400 kilos. of pig-iron were melted with 2,328 kilos. of limestone, and 2032 kilos. of ore were then suddenly added, the reaction was very rapid; after 30 minutes the bath foamed and the slag rose to the level of the doors, and in ten minutes more the ore had completely disappeared, whilst samples showed that the carbon, silicon, manganese, and phosphorus had been reduced from 3.66, 1.33, 2.71, and 0.12 to 3.14, 0.02, 0.33, and 0.01 per cent. The reaction had, without doubt, raised the temperature of the bath, for the furnace gases themselves would not so rapidly have melted and completed the reaction of such a large quantity of ore. Experiments with fluid pig-iron showed that the removal of silicon, manganese and phosphorus is extremely rapid—4590 kilos. of ore were spread on the furnace bottom, then

two ladles of ten tons each of fluid pig-iron were poured in as follows:—

	Si.	Mn.	P.	C.
4h. 36m. to 4h. 38m., 10 tons containing	1.61	2.73	0.27	4.06
4h. 45m., sample contained	0.04	0.24	0.08	8.42
4h. 58m. to 5h. 00m., 10 tons containing	1.63	2.86	0.27	4.06
5h. 8m., sample contained	0.04	0.41	0.08	3.47

It appears, then, that the exothermic reactions occur first, and that the speed of reaction is similar to that found in ordinary aqueous solutions, i.e., the reaction occurs practically as rapidly as mixture of the reacting solutions can be effected. Here, the mixture is not nearly so perfect as that between two liquids, one reacting substance being to start with solid, but the retardation due to this is compensated by the high temperature.

4. *Experiments without the aid of Furnace Heat.*—From the above it would seem that the removal of silicon, manganese, and phosphorus might be effected without the aid of the furnace, and experiments showed that when ore was placed in the transport ladle used to carry the iron from the blast-furnace to the Siemens-Martin furnace, and fluid pig-iron poured upon it, a small amount of slag soon formed, and then reaction set in and became continuously more rapid, being controllable by slackening or quickening the iron-supply. In one such experiment the silicon, manganese, phosphorus and carbon were reduced from 3.50, 0.88, 0.46, 3.93 to 0.42, 0.33, 0.36, 3.74 per cent.; and of the iron of the ore, 37.2 per cent. went into the metal, 60 per cent. went as ferric oxide into the slag, and 2.8 per cent. remained as ferric oxide. Calculation of the heat result showed that (if the estimates for specific heats of iron and slag be correct) the temperature rose during the operation by 125° C. This experiment was carried out in an acid-lined ladle, yet a notable oxidation and removal of phosphorus occurred. A similar experiment in a basic-lined Siemens-Martin furnace with the gas shut off, showed a reduction of phosphorus from 0.36 in the original metal to 0.14 immediately after pouring in the charge, and to 0.09 after ten minutes more.

5. *The Function of the Furnace.*—This would appear, then, to be to furnish the high-temperature heat needed for the separation of the carbon. But it is probably not desirable to remove the other impurities separately outside the furnace, for not only does their removal impose no burden on the furnace, but the heat evolution thereby caused favours and renders more rapid the removal of the carbon. Moreover, silica is needed to bring the ferric oxide into solution, and hence an iron with 1—1.25 per cent. of silicon is most suitable in the furnace. The added lime serves in due course to substitute the ferrous oxide in the slag, and render it available for the oxidation of the carbon, and the rate at which a lime-ferrous oxide-silica slag will dissolve ferric oxide and that at which carbon will reduce the dissolved oxide balance one another in the furnace, so that while the carbon is being steadily removed the iron-content of the slag remains constant.

6. *Influence of the Impurities on the Heat needed in the Process.*—The highest temperature in the furnace is estimated by different authorities at from 1718° to 1788° C., that of the finished steel at discharge from 1486° to 1586° C. Assuming 1200° C. as the temperature of the entering fluid pig-iron, and the specific heats of iron and of slag as 0.21 and $1\frac{1}{2}$ times that figure, we find that to raise the temperature of iron and slag from that of the entering pig-iron to that of the finished steel we need 100 calories per kilo. of iron and 150 per kilo. of slag. The limestone for the slag requires per kilo., for heating to 1200° C., dissociation, and fusion, 716 calories per kilo.; 1 kilo. of silica in the slag requiring (for Ca_2SiO_4) 4.46 kilos. of limestone. Calculations on similar lines to those above, but taking account in the case of each constituent of the heat required for the equivalent amount of limestone, show as follows the effects in the furnace:—

Substance, 1 kilo.	Requires.		Yields.		Heat Result.
	Ferric Oxide	Lime- stone	Slag.	Metals*	
	Kilos.	Kilos.	Kilos.	Kilos.	Calories.
Silicon	3.81	7.40	10.70	1.56	-4964
Phosphorus	4.30	6.70	2.68	2.01	-5932
			accounted for under Si		
Manganese	0.97	—	—	0.32	+ 228
Carbon	4.04	0.78	1.35	1.31	-3751
Silica in ore	—	3.46	5.00	—	-4500

* Difference between amount of reduced iron added to metal and amount of constituent removed.

From these figures the results of using any given pig-iron in the furnace can be calculated. Thus, 300 kilos. of metal containing 1.03, 0.14, 1.82, and 4.21 per cent. of silicon, phosphorus, manganese and carbon respectively, require 23.30 kilos. of ferric oxide, or 23.56 kilos. of ore containing 98.9 per cent. of ferric oxide and 1 per cent. of silica. The slag formed will weigh 6.82 kilos., and the addition to the metal will be 6.82 kilos., while the heat required will be 22,378 calories (not including that for raising the temperature of the metal). This works out to 209 cal. per kilo. of finished steel, or, adding the heat needed to raise 6.82 kilos. of iron from 0° and 100 kilos. from 1200° C. to the final temperature, 325 cal. per kilo. of steel.

7. *Examples from Practice*—The difficulty in practice with the fluid pig-iron process is in ascertaining the composition of the iron. There is no time for analysis, and the only plan is to keep the ore well under the necessary quantity at first, and add more as required. Using the metal and ore mentioned immediately above, 2330 kilos. of limestone and 5720 of ore were used, 330 kilos. and 180 kilos. of ore being added later. The metal used was 26,200 kilos. of the fluid pig-iron and 200 kilos. of 80 per cent. ferromanganese. The steel contained 0.00, 0.02, 0.71, 0.00 per cent. of silicon, phosphorus, manganese and carbon respectively. The ore used was 23.60 per cent. of the metal charged, while 23.56 per cent. was calculated. The slag (calculated as before from the silica charged) weighed 18.33 per cent. of the metal, against 18.23 in the former calculation. The iron reduced and recovered was 88.7 per cent. of that in the ore, or 3830 kilos.; and 3900 kilos. of impurities were removed from the pig-iron, so that the metal gained 1930 kilos., or 7.3 per cent., against 6.82 per cent. calculated. The calculated results, therefore, are well borne out by practice.

8. *Heat comparison of Scrap and Ore processes.*—The charge just referred to and the scrap charge described early in the paper were compared as to the quantities of heat actually in the products, those yielded by the reactions in the process, and hence by difference those supplied by the furnace. In the scrap process, 19,284 kilos. of steel were produced with a heat supply from the furnace of 318 cal. per kilo.; in the ore process, 28,330 kilos., with a heat supply of 326 cal. per kilo.,—almost identical with the other. But the actual yield of the furnace was much higher in the second case, for, the pig-iron being fluid to start with, the time was relatively shorter. The scrap process lasted 277 minutes, or yielded 70 kilos. per minute; the other lasted 300 minutes, or yielded 94 kilos. per minute. Even though it be assumed that the heat-content of the fluid pig-iron to start with was 285 cal., instead of 250 as assumed in the calculations, the utilisation of the furnace heat would still appear to be better in that process than in the scrap process in the proportion of 27.7 to 22.2; and the author believes the reasons to be (1) that the furnaces are less cooled in the ore process, and the perfect combustion of the gases less interrupted; (2) that throughout the ore process the bath is in constant agitation, ensuring a more thorough absorption of heat; (3) that this heat does not simply produce rise of temperature, but is absorbed in quickening the carbon removal, and the temperature gradually rises as the carbon disappears; there is no fear of overheating as long as both carbon and ore exist.

The same Siemens-Martin furnace, which gave a monthly

production of 1600 tons with the scrap process, is now giving 3000 tons with the fluid pig-iron and ore process, and the yield is still improving. The author considers, therefore, that the ordinary basic Siemens-Martin furnace is capable of giving quite as good results as are claimed for the Talbot or the Bertrand Thiel process.—J. T. D.

Blast-Furnace: Gases of — during occurrence of Scuffs in the Furnace Throat. E. Kravuk, Stahl u. Eisen, 1905, 25, 1437—1439.

The author finds that scuffs are indicated in gas-samples taken at the furnace-throat, by (1) an increase in oxygen; (2) great variations in carbon monoxide and dioxide; (3) the appearance of heavy hydrocarbons. The high oxygen-content probably arises from portions of the blast finding their way through the sintered mass without action. The variations in the oxides of carbon arise from irregularities in the reduction process; and the carbon monoxide is probably produced by the reaction of the dioxide on the carbon-dust formed at such times. The same carbon-dust, together with hydrogen from the moisture in the blast, the ore, and the coke, may produce the hydrocarbons. Regular analysis of the furnace-gases will at once indicate irregularities in the working of the furnace, and probably allow of forecasting the possible occurrence of explosions.—J. T. D.

Platinum: Sublimation of — below its Melting Point. A. Guntz and H. Bassett, Jun. Bull. Soc. Chim., 1905, 33, 1306—1308.

A GREY crystalline deposit, which had formed on the carbon in an electric furnace which was heated by platinum wire, was found to consist of pure platinum; since the temperature of the furnace varied between 1000° and 1300° C., sublimation had occurred. The rate of loss for a 0.3 mm. diameter platinum wire was about one-tenthousandth of its weight per hour.—T. F. B.

Platinum Ware: Repairing —. E. J. Sweetland, Eng. and Mining J., 1905, 80, 1163.

For repairing platinum ware by welding, the author uses a block or anvil prepared by mixing plaster of Paris and powdered pumice stone into a stiff paste with water and moulding it into the desired form. The article to be repaired is placed over the block and the cleaned surfaces of the pieces of metal to be welded are heated to incandescence and gently hammered together.—A. S.

Aluminium and its Alloys: Analysis of —. C. Formenti, XXIII., page 92.

Mineral Industry of New Zealand. Bd. of Trade J., Jan. 1, 1906.

The following particulars regarding gold and other minerals in New Zealand are taken from the recently-issued report of the Department of Mines for 1904:—

The return of gold exported for 1904 shows a falling-off in value (as compared with that of the previous year) of £50,330, the figures being £1,987,501 for 1904, as against £2,037,831 for 1903.

Scheelite is being worked in the vicinity of Maerua's and Mount Highlay in Otago. As the demand for scheelite containing not less than 60 per cent. of tungstic acid is steadily increasing, and much greater quantities than have hitherto been available are now being inquired for, the matter is receiving greater attention in the district, and it appears more than probable that the export of this mineral will show a decided increase within the next few years.

Small quantities of *platinum* are obtained at the Round Hill Gold Mining Company's works at Round Hill, South Land. A little is also reported as being present in the wash at the Takaka Hydraulic Claim, but up to the present no attempt has been made to save it commercially.

Hematite paint is made from the iron ores of Parapara, and also at Thames. The crude mineral is also supplied from a deposit at one of the South Land lignite mines for use as a pigment for colouring paper at the Mataura Paper Mills.

The *rock-phosphate* deposits near Milton, Otago, are being worked, and the stone, after calcination, is treated

at the Burnside Chemical Works and put on the market as a fertiliser.

Copper.—The Mineral Belt Copper Mining Co., Ltd., commenced operations upon the Anisced Valley section of their property in Jan., 1904. So far as can be judged at present they should have no trouble in maintaining a fair grade of output, as assays range from 5 to 26 per cent. of copper, and the ore bodies are from 2 ft. to 10 ft. wide.

Deposits of copper ore are known to exist at several places in both Islands, but their extent and value are, generally speaking, as yet unproved. A syndicate has been formed for the purpose of exploiting the deposits at Moko Creek, near Queenstown, Otago.

Petroleum.—A borehole has been put down at Moturua, near New Plymouth Breakwater, to a depth of 2100 ft. Before reaching this depth a blow of natural gas and water was met with, and later on the strata drilled through gave evidence of the ground carrying crude petroleum to some extent. [T.R.]

Mineral Exports from Brazil. Bd. of Trade J., Jan. 11, 1906.

THE following table showing the exports of minerals from Brazil during the years 1902—4 is taken from the "Brazilian Review" of Dec. 5 last:—

	1902	1903	1904
Monazite . . . Tons	1,205	3,239	4,860
Manganese . . .	157,295	161,926	208,260
Mica and talc . . .	11	7	11
Copper ore . . .	211	316	610
Gold bar . . . Grammes	3,089,082	4,323,043	3,871,476
Diamonds . . . Value £	65,708	61,167	29,001
Carbonates . . .	41,227	55,302	26,587
Other precious stones . . .	3,000	6,813	10,369
Platinum . . . Grammes	—	1,715	2,132
Rock crystal . . . Tons	36	23	37
Agate . . .	81	71	54

[T.R.]

Mineral Production of Tasmania. Bd. of Trade J., Jan. 4, 1906.

THE following table, compiled by the Government geologist, shows, as far as can be ascertained, the quantities and values of metals and minerals produced in Tasmania in the quarters ending March 31 and June 30, 1905:—

	March Quarter, 1905	June Quarter, 1905.
Gold,* fine, won	112s	£
Silver and lead ore,† raised	Tons	Tons
Blister copper,† produced	1,907	1,981
Copper ore and native copper produced	215	319
Tin ore	928	741
Iron ore	1,801	1,700
Coal	15,283	12,372
Wolfram ore	0	7
Bismuth ore	15	200
Total value	383,861	373,370

* Including gold contained in blister copper and silver lead bullion.

† Value of gold contents deducted.

[T.R.]

Iron Drillings; Standardised Cast.—Amer. Foundrymen's Assoc., Dec. 28, 1905.

THE Standardising Bureau of the American Foundrymen's Association has been taken over by the Government, and the standardised drillings of cast iron are now to be obtained from the Bureau of Standards of the Department of Commerce and Labour, Washington, where all orders

must be sent. The charge is 2 dols. per sample of 150 grms., or 5 dols. for three samples of the same weight. [T.R.]

Mineral Production of Italy. Eng. and Mining J., Dec. 23, 1905.

RASSSEGNA MINERARIA publishes the following statistics of mineral and metal production of Italy for 1903 and 1904. The quantities are in metric tons unless otherwise specified:—

	1903.	1904.
ORES OF		
Antimony	6,027	5,712
Silver	405	143
Arsenic	50	80
Bismuth	374,790	409,480
Manganese	1,030	2,836
Mercury	55,528	60,403
Gold	5,734	6,749
Lead	49,143	42,846
Copper	118,823	157,503
Sulphur	3,090,532	3,539,444
Zinc	157,521	148,365
Metals		
Cast and wrought iron	30,744	12,508
Wrought iron	177,392	381,335
Rolling steel	154,131	177,080
Turned plates	11,275	16,015
Antimony	905	836
Silver, kilos	24,988	24,943
Mercury	312	352
Gold, kilos	63	10
Lead	22,126	23,476
Copper and its alloys	11,217	11,873
Tin	16	15
Zinc	126	180
Non-metallic		
Boric acid	2,583	3,024
Coal, lignite, &c	346,887	362,151
Graphite	7,920	9,765
Crude petroleum	2,486	3,544
Pyrites	191,155	112,004
Asphaltic rock	89,178	111,360
Asphaltum, mastic and bitumen	35,757	39,817
Coal bituminous	724,063	903,310
Crude sulphur	553,751	527,564
Refined sulphur	139,404	163,695
Ground sulphur	139,376	189,206
Pulverized talc	6,300	6,740

The total value of the 1904 output was 294,472,153 lire (£1,778,880), an increase of 20,790,059 lire over that of the previous year. [T.R.]

	March Quarter, 1905	June Quarter, 1905.
Quantity	Value	Quantity, Value.
Gold,* fine, won	16,170	68,657
Silver and lead ore,† raised	17,701	54,896
Blister copper,† produced	1,907	1,981

SEE U.S. Pats. 804,692 and 804,693 of 1905; this J., 1905, 1310.—T. F. B.

Iron Oxide; Preparing — for Treatment in Furnaces.
U. Wedge, Ardmore, Pa., U.S.A. Eng. Pat. 16,234, Aug. 9, 1905.

SEE U.S. Pat. 800,698 of 1905; this J., 1905, 1113.—T.F.B.

Substance, 1 kilo.	Requires.		Yields.		Heat Result.
	Ferric Oxide	Lime- stone	Slag.	Metals*	
	Kilos.	Kilos.	Kilos.	Kilos.	Calories.
Silicon	3.81	7.40	10.70	1.56	-4964
Phosphorus	4.30	6.70	2.68	2.01	-5932
			accounted for under Si		
Manganese	0.97	—	—	0.32	+ 228
Carbon	4.04	0.78	1.35	1.31	-3751
Silica in ore	—	3.46	5.00	—	-4500

* Difference between amount of reduced iron added to metal and amount of constituent removed.

From these figures the results of using any given pig-iron in the furnace can be calculated. Thus, 300 kilos. of metal containing 1.03, 0.14, 1.82, and 4.21 per cent. of silicon, phosphorus, manganese and carbon respectively, require 23.30 kilos. of ferric oxide, or 23.56 kilos. of ore containing 98.9 per cent. of ferric oxide and 1 per cent. of silica. The slag formed will weigh 6.82 kilos., and the addition to the metal will be 6.82 kilos., while the heat required will be 22,378 calories (not including that for raising the temperature of the metal). This works out to 209 cal. per kilo. of finished steel, or, adding the heat needed to raise 6.82 kilos. of iron from 0° and 100 kilos. from 1200° C. to the final temperature, 325 cal. per kilo. of steel.

7. *Examples from Practice*—The difficulty in practice with the fluid pig-iron process is in ascertaining the composition of the iron. There is no time for analysis, and the only plan is to keep the ore well under the necessary quantity at first, and add more as required. Using the metal and ore mentioned immediately above, 2330 kilos. of limestone and 5720 of ore were used, 330 kilos. and 180 kilos. of ore being added later. The metal used was 26,200 kilos. of the fluid pig-iron and 200 kilos. of 80 per cent. ferromanganese. The steel contained 0.00, 0.02, 0.71, 0.09 per cent. of silicon, phosphorus, manganese and carbon respectively. The ore used was 23.60 per cent. of the metal charged, while 23.56 per cent. was calculated. The slag (calculated as before from the silica charged) weighed 18.33 per cent. of the metal, against 18.23 in the former calculation. The iron reduced and recovered was 88.7 per cent. of that in the ore, or 3830 kilos.; and 3900 kilos. of impurities were removed from the pig-iron, so that the metal gained 1930 kilos., or 7.3 per cent., against 6.82 per cent. calculated. The calculated results, therefore, are well borne out by practice.

8. *Heat comparison of Scrap and Ore processes.*—The charge just referred to and the scrap charge described early in the paper were compared as to the quantities of heat actually in the products, those yielded by the reactions in the process, and hence by difference those supplied by the furnace. In the scrap process, 19,284 kilos. of steel were produced with a heat supply from the furnace of 318 cal. per kilo.; in the ore process, 28,330 kilos., with a heat supply of 326 cal. per kilo., almost identical with the other. But the actual yield of the furnace was much higher in the second case, for, the pig-iron being fluid to start with, the time was relatively shorter. The scrap process lasted 277 minutes, or yielded 70 kilos. per minute; the other lasted 300 minutes, or yielded 94 kilos. per minute. Even though it be assumed that the heat-content of the fluid pig-iron to start with was 285 cal., instead of 250 as assumed in the calculations, the utilisation of the furnace heat would still appear to be better in that process than in the scrap process in the proportion of 27.7 to 22.2; and the author believes the reasons to be (1) that the furnaces are less cooled in the ore process, and the perfect combustion of the gases less interrupted; (2) that throughout the ore process the bath is in constant agitation, ensuring a more thorough absorption of heat; (3) that this heat does not simply produce rise of temperature, but is absorbed in quickening the carbon removal, and the temperature gradually rises as the carbon disappears; there is no fear of overheating as long as both carbon and ore exist.

The same Siemens-Martin furnace, which gave a monthly

production of 1600 tons with the scrap process, is now giving 3000 tons with the fluid pig-iron and ore process, and the yield is still improving. The author considers, therefore, that the ordinary basic Siemens-Martin furnace is capable of giving quite as good results as are claimed for the Talbot or the Bertrand Thiel process.—J. T. D.

Blast-Furnace: Gases of — during occurrence of Scuffs in the Furnace Throat. E. Kravuk, Stahl u. Eisen, 1905, 25, 1437—1439.

The author finds that scuffs are indicated in gas-samples taken at the furnace-throat, by (1) an increase in oxygen; (2) great variations in carbon monoxide and dioxide; (3) the appearance of heavy hydrocarbons. The high oxygen-content probably arises from portions of the blast finding their way through the sintered mass without action. The variations in the oxides of carbon arise from irregularities in the reduction process; and the carbon monoxide is probably produced by the reaction of the dioxide on the carbon-dust formed at such times. The same carbon-dust, together with hydrogen from the moisture in the blast, the ore, and the coke, may produce the hydrocarbons. Regular analysis of the furnace-gases will at once indicate irregularities in the working of the furnace, and probably allow of forecasting the possible occurrence of explosions.—J. T. D.

Platinum: Sublimation of — below its Melting Point. A. Guntz and H. Bassett, Jun. Bull. Soc. Chim., 1905, 33, 1306—1308.

A GREY crystalline deposit, which had formed on the carbon in an electric furnace which was heated by platinum wire, was found to consist of pure platinum; since the temperature of the furnace varied between 1000° and 1300° C., sublimation had occurred. The rate of loss for a 0.3 mm. diameter platinum wire was about one-tenthousandth of its weight per hour.—T. F. B.

Platinum Ware: Repairing —. E. J. Sweetland, Eng. and Mining J., 1905, 80, 1163.

For repairing platinum ware by welding, the author uses a block or anvil prepared by mixing plaster of Paris and powdered pumice stone into a stiff paste with water and moulding it into the desired form. The article to be repaired is placed over the block and the cleaned surfaces of the pieces of metal to be welded are heated to incandescence and gently hammered together.—A. S.

Aluminium and its Alloys: Analysis of —. C. Formenti, XXIII., page 92.

Mineral Industry of New Zealand. Bd. of Trade J., Jan. 1, 1906.

The following particulars regarding gold and other minerals in New Zealand are taken from the recently-issued report of the Department of Mines for 1904:—

The return of gold exported for 1904 shows a falling-off in value (as compared with that of the previous year) of £50,330, the figures being £1,987,501 for 1904, as against £2,037,831 for 1903.

Scheelite is being worked in the vicinity of Maerua's and Mount Highlay in Otago. As the demand for scheelite containing not less than 60 per cent. of tungstic acid is steadily increasing, and much greater quantities than have hitherto been available are now being inquired for, the matter is receiving greater attention in the district, and it appears more than probable that the export of this mineral will show a decided increase within the next few years.

Small quantities of *platinum* are obtained at the Round Hill Gold Mining Company's works at Round Hill, South Land. A little is also reported as being present in the wash at the Takaka Hydraulic Claim, but up to the present no attempt has been made to save it commercially.

Hematite paint is made from the iron ores of Parapara, and also at Thames. The crude mineral is also supplied from a deposit at one of the South Land lignite mines for use as a pigment for colouring paper at the Mataura Paper Mills.

The *rock-phosphate* deposits near Milton, Otago, are being worked, and the stone, after calcination, is treated

rounded by a cotton fabric. The electrolyte must be constantly circulated and always kept acid with carbonic acid, as otherwise the anode becomes coated with a sticky yellow substance which increases the resistance. A current of 1 ampère per sq. dm. is used, the voltage being 1.5 to 2 volts. As anode melted scrap copper or cement copper is used, the vats being made of tarred or paraffined wood. The carbonate formed is dissolved in sulphuric acid at 26° B. According to the author, the actual cost of the process for 100 kilos. of copper sulphate produced is 8.70 marks.—A. G. L.

ERRATUM.

Nitrogen: Utilisation of Atmospheric ——. O. N. Wutt.

This J., 1906, 27, col. 1. Paragraph beginning l. 12, and ending l. 9 from bottom include in the preceding parenthesis, but word as follows: "In accordance with a suggestion by R. Messel to use basic calcium nitrate, the normal calcium nitrate is," &c.

Plumbism due to Electrolysis. B. Latham.
XVIII, page 85.

ENGLISH PATENT.

Fish-oil, [Electrical] Process for Eliminating the Odour of ——. A. de Hemptinne. Eng. Pat. 12,625, June 16, 1905. XII, page 80.

UNITED STATES PATENTS.

Liquids; [Electrical] Apparatus for Sterilising, Purifying, and Ageing ——. R. C. Turner Assignor to C. E. Turner. U.S. Pat. Re-issue, 12,421, Dec. 12, 1906. XVIII, page 86.

Ozone: Apparatus for Producing ——. W. P. Rice, Assignor to The National Ozono Co., both of Chicago, Ill. U.S. Pat. 807,964, Dec. 19, 1905.

Air is forced under pressure through a closed box formed by two thin parallel flat metal plates, against the electrodes, and joined at their margins by insulating strips forming air-tight joints. The plates are separated by a narrow air-gap, and a flat dielectric is interposed between them and extends beyond the parallel parts of the plates. The outer surfaces of the electrodes are exposed freely to the atmosphere.—B. N.

FRENCH PATENTS.

Carbon Filaments for Incandescence Lamps; Manufacture of ——. Cie. Franc. pour l'Exploit. des Procédés Thomson-Houston. Fr. Pat. 357,254, Aug. 26, 1905. II., page 62.

Voltaic Arcs; Production of Stable ——. of Great Size. Soc. Badische Anilin und Soda Fabrik. Fr. Pat. 357,358, Aug. 30, 1905. Under Int. Conv., June 23, 1905.

The object of the invention is the production of voltaic arcs of great size by the aid of currents of small tensions. An insulated electrode is fixed within a tube near to one extremity, and gas, in the form of eddies, is passed between the tube and the electrode. The tube itself is bound to the other pole of the source of current, or an electrode of special form may be used.—B. N.

Electrolysis; Improved Process and Apparatus for ——. L. A. P. Liénard. Fr. Pat. 350,862, Aug. 5, 1905.

This invention relates to the electrolysis of salts, more particularly of sodium chloride, for the production of sodium hydroxide and chlorine. Each electrode is enclosed in an envelope, preferably of asbestos, the anode envelopes being open at the base, whilst the cathode envelopes are thicker and consequently less porous than those used for the anodes. The electrodes, and consequently the apparatus, are short in height, and the anodes are so mounted that thin sheets of platinum may be employed. Notches are cut near to each other in the vertical sides of the sheet-iron box forming the cathode, the bottoms of the notches being as nearly as possible on a

straight horizontal line. The sodium hydroxide produced is thus rapidly removed from the upper surface of the cathode liquid to the interior of the cathode box, and the stay of the hydroxide in the apparatus is thus reduced to a minimum.—B. N.

Ozonisers with Electric Discharges; Impts. in ——. H. J. Wessels de Frisco. Fr. Pat. 357,136, Aug. 23, 1905.

The ozoniser is composed of an envelope, with cooled walls, constructed of a substance impermeable to ultra-violet rays, and is provided with one or more forms of apparatus for producing rays of short wave length by means of electricity.—B. N.

(B.)—ELECTRO-METALLURGY.

Zinc Fuses. A. Schwartz and W. H. N. James. Electrician, 1905, 56, 184.

The authors have studied the behaviour of zinc fuses in the form of strips when used as thermal cut-outs in electric circuits. Zinc shows very little deterioration; when run continuously at 90 or even 95 per cent. of the normal fusing current; the oxidation is very slight and the final resistance of the strip is practically the same as its initial resistance. This is a marked advantage in comparison with copper, which becomes red hot with about 75 per cent. of its normal fusing current and above this point oxidises rapidly. Zinc has, however, certain disadvantages. The mass of the fuse is about 3.5 times, the volume 4.4 times, that of a copper fuse of the same length and for the same fusing current. Moreover, on disruption, the metal is distributed in the form of globules, which are not only red hot, but which continue to burn in air, being accompanied by dense white fumes which deposit heavily on contiguous surfaces.—R. S. H.

Aluminium Fuses. A. Schwartz and W. H. N. James. Electrician, 1906, 56, 408—409.

Fuses of aluminium wire, particularly of small diameter, are unreliable owing to the molten metal being held up by the skin of oxide which forms on the surface. The present study was therefore limited to the metal in the form of strip. The metal attains a dull red heat just before fusion, and on disruption will throw off burning globules of metal a distance of several feet even on a low-tension circuit. Aluminium, zinc and cadmium, being highly electro-positive to copper and brass, are liable to considerable corrosion of the contacts when used in damp situations. Consequently their application is somewhat limited.

—R. S. H.

Tantalum, Production and Properties of ——. I. Nordonskjöld. Tekn. Tidskrift, Stockholm, 1905, Chem. and Mining Sect., 26—28. Proc. Inst. Civ. Eng., 1905, 162, 39—40 (see this J., 1904, 140).

METALLIC tantalum can be prepared by Goldschmidt's aluminothermic method, but it is then largely alloyed with aluminium, and is brittle. Pure tantalum, which is rather hard and very malleable, is obtained by passing an electric current through the oxide in a vacuum, or by smelting the oxide *in vacuo* by the aid of the electric arc. Pure tantalum has a specific heat of 0.0305. The cast metal has the sp. gr. 16.64. Specific electrical resistance of a wire 1 m. long and 1 sq. mm. cross-section, 0.165 ohm, with an average rise of 0.3 per cent. per degree of temperature between 0° and 100° C., and of 0.26 per cent. between 0° and 350° C.; tensile strength of a wire of 1 mm. diameter, 93 kilos per sq. mm.; elongation, 1—2 per cent.; modulus of elasticity of a wire of 0.08 mm. diameter, 19,000 kilos. per sq. mm.

Tantalum takes up hydrogen readily, but its properties do not appear to be appreciably affected thereby; the hydrogen can be expelled only partially and with difficulty even by melting the metal. Oxygen has little action on tantalum; at 400° C. it is tarnished slightly yellow, the colour changing to blue at a low red heat, whilst the wire ultimately becomes coated with a white layer of tantalum pentoxide. If an electric current

be sent through a tantalum wire placed under the bell of an air-pump into which oxygen is gradually admitted, no action takes place until the pressure reaches 20 mm. of mercury, and even at higher pressures oxidation only proceeds very slowly. Tantalum is not acted upon by acids and alkalis. On heating it in nitrogen, the gas is absorbed, and the tantalum becomes brittle. It can be alloyed with iron, and hardens the latter just as vanadium does. Carbon renders tantalum hard and brittle.—A. S.

Barium; Preparation of Pure ——. Guntz. *Comptes rend.*, 1905, 141, 1240—1241.

THE author's method (this J., 1902, 54) will not yield a metal purer than 98.5 per cent. But by dissociation of the hydride he has obtained a practically pure metal. Preparing the metal as described (*loc. cit.*) and using a flat-bottomed boat and a quantity of amalgam to yield not more than 20 grms. of metal, he allows hydrogen to enter and to be absorbed for several hours at 900° C., and then gradually heating to the melting-point of the hydride formed (1200° C.), obtains a hydride free from mercury. This, after cooling, is heated to 1200° C. *in vacuo*, in an iron tube open at one end and enclosed in a porcelain tube connected with a mercury-pump. When dissociation is complete, the barium begins to distil, and is collected in a water-cooled polished steel tube placed near the mouth of the iron tube. The metal is silver-white, and has a density of 3.78; the density of the hydride is higher than that of the metal, *viz.*, 4.21. Pure metallic strontium has been similarly prepared. J. T. D.

UNITED STATES PATENTS.

Electrolytic Deposits; Process of Obtaining Marketable ——. P. Steenhit, Assignor to M. P. Lloyd, Brussels. U.S. Pat. 807,973, Dec. 19, 1905.

SEE Eng. Pat. 16,988 of 1903; this J., 1903, 1356.—T.F.B.

Metals [Electrolytically]; Galvanising ——. G. L. Meaker, Evanston, Ill., Assignor to The American Steel and Wire Co., New Jersey. U.S. Pat. 808,103, Dec. 26, 1905.

THE metal is subjected to the action of an electric current in an electroplating apparatus, the electrolyte consisting of a solution of zinc chloride, zinc sulphate and a small proportion of a vegetable acid.—B. N.

Galvanoplastic Deposits; Method of Separating ——. from Metal Matrices. E. Albert, Munich, Germany. Assignor to F. Wesel, New York. U.S. Pat. 808,331, Dec. 26, 1905.

A METALLIC bath is heated to a temperature lower than the melting point of the matrix, and the latter and the deposit are suddenly heated by floating them on the molten metal.—B. N.

Decarburising [Ferrochrome]; Process of ——. F. von Kugelgen and G. O. Seward, Holcombs Rock, Va., Assignors to The Willson Aluminium Co., New York. U.S. Pat. 807,034, Dec. 12, 1905.

A METAL or alloy, *e.g.*, ferrochrome, low in carbon, is produced by first reducing the ore in presence of carbonaceous material to obtain a product high in carbon, and then decarburising the same by using it as an electrode and fusing it in absence of carbonaceous material and in presence of a substance having a high affinity for carbon.—A. S.

Calcium [Electrolytically]; Production of Metallic ——. W. Borchers and L. Stookem, Aachen, Germany. U.S. Pat. 808,066, Dec. 26, 1905.

THIS invention relates to a process for the production of metallic calcium by the fusion and electrolysis of anhydrous calcium salts. The small cathode is kept sufficiently cool to prevent the calcium, as it deposits, from molting, and the metal is thus obtained in a spongy state. The spongy calcium is pressed whilst under the molten calcium salt, and thus withdrawn from the bath.—B. N.

FRENCH PATENTS.

Ore Treatment; Magnetic Separator for ——. Soc. Maschinenbau Anstalt Humboldt. Fr. Pat. 357,216, Aug. 5, 1905.

A NON-MAGNETIC drum revolves around a fixed permanent magnet, a "magnetic star," having radial projections, influencing about three-fourths of the circumference of the drum, the projections being alternately positive and negative. Between the magnetic arms is a series of trapezoidal projections which become magnetised; outside the drum is a skeleton or framework of iron having many rectangular openings. The whole arrangement is placed above three collectors or bins which receive the various products of the operation. The material to be treated is fed on to the rising shoulder of the revolving drum just above the first of the magnetic radii by means of a shoot which, aided by the magnetised projections, holds the variously magnetic particles as they are carried around by the drum, whilst the non-magnetic particles fall away at once into the first of the collectors. In their passage over the remaining alternately magnetised radii, the more magnetic particles are separated from those which are less magnetic and each product finally falls into its own collector.—J. H. C.

Metals; [Electrolytic] Method of Purifying ——. H. M. Chance. Fr. Pat. 357,466, Sept. 4, 1905.

SEE U.S. Pat. 800,984 of 1905; this J., 1905, 1116.—T.F.B.

Etching [Designs on] Metals, and especially Printing Cylinders [Electrolytically]. J. A. Dejev. First Addition dated Aug. 16, 1905, to Fr. Pat. 335,041, Sept. 18, 1903 (this J., 1904, 327).

THE addition relates to the use of insoluble anodes of platinum, carbon, &c., for the electrolytic deposition of tin, iron, copper, lead, &c., and to the application of this process to photo-engraving and all work of engraving on metals.—B. N.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

(Continued from page 32.)

ENGLISH PATENTS.

Sewage Sludge; Method and Apparatus for Recovering Fatty and Oily Matter from ——. The Mayor, Aldermen and Citizens of Bradford, J. Garfield and J. Grossmann, Manchester. Eng. Pat. 29,558, Dec. 31, 1904. XVIII.B., page 86.

Fish-oil; [Electrical] Process for Eliminating the Odour of ——. A. de Hemptinne, Gand, Belgium. Eng. Pat. 12,525, June 10, 1905.

THE oil to be treated is placed in a rotating cylinder in which is arranged a series of parallel plates consisting alternately of metal and glass. The metal plates are connected with a supply of electricity and the drum is filled with an atmosphere of hydrogen. As the drum rotates, the oil is caught up by a number of gutters fixed to the internal wall of the drum and is sprinkled over the plates. The action of the silent electric discharge in the atmosphere of hydrogen is stated to remove all odour from the fish-oil. (See also Eng. Pat. 1572, 1905; this J., 1905, 448.)—W. P. S.

UNITED STATES PATENTS.

Oil, Grease and the like from Oil-Bearing Material; Process of Extracting ——. F. J. Maywald, Assignor to E. H. Fallows, both of New York. U.S. Pat. 807,567, Dec. 19, 1905.

THIS invention relates to a process of extracting oil, grease, or the like from water or similar liquid, or from material floating or in suspension in the liquid. Carbon tetrachloride is added and allowed to descend through the mass;

the heavy layer is run off and the carbon tetrachloride separated from the dissolved grease or oil by distillation.

—B. N.

Cooling and Drying Oil-Cake; Apparatus for —. A. W. French, Piqua, Ohio. U.S. Pat. 808,081, Dec. 26, 1905.

THE material to be cooled and dried is fed into an upright cylinder, having a conical bottom, provided with an internal conduit for the treating agent, and suspended from one arm of a weighted lever. A positively acting rotary discharge drum is fixed to the bottom of the cone and receives motion from a pulley and belt. A bolt-tightening device, actuated by a rod attached to the weighted lever, presses on the belt, and when the cylinder is full, and consequently heavy, the lever is moved, the bolt tightened and the discharge drum commences to work. As soon as the cylinder is lightened, the lever moves again, the bolt becomes slack and the discharge is stopped until the cylinder is filled up again. In this way the weight of material in the cylinder is kept nearly constant.—W. H. C.

Soap Machine. N. G. Knight, Crestline, Ohio. U.S. Pat. 806,816, Dec. 12, 1905.

THE apparatus claimed consists of a jacketed vessel, in which revolves a shaft carrying mixing blades. There are also buckets carrying an internal gear, which rotate about the shaft, a gear wheel on one end of the shaft, and a pinion on the inner face of the head of the vessel meshing with the gear-wheel and the internal gear of the buckets.

—C. A. M.

FRENCH PATENT.

Oils; Process and Apparatus for Extracting —. W. H. Gessner and A. R. Brandy. Fr. Pat. 357,329, Aug. 29, 1905.

THE vegetable seeds, &c., are treated with a solution of a silicate of sodium or other alkali metal to liberate the oil, the process being facilitated by a preliminary crushing and drying of the material. The mass, after being boiled with the silicate, is plunged into hot water or a suitable aqueous solution, with the result that the oil separates out on the surface, whilst the residuo falls to the bottom. The apparatus claimed for carrying out this process comprises a kettle, a drying apparatus and a separator, the latter being provided with internal partitions to facilitate the separation of the oil.—C. A. M.

FRENCH PATENT.

Paints, Varnishes, &c., Rendered Non-inflammable by the Addition of Carbon Tetrachloride. E. D. P. Fournier. Fr. Pat. 350,314, Nov. 16, 1904.

THE composition of a non-inflammable paint is claimed. It consists of potassium or sodium silicate, 400 parts; 5

per cent. borax solution, 100 parts; glycerin containing 5 per cent. of carbon tetrachloride, 180 parts. This liquid is then mixed with suitable proportions of pigments, &c. The addition of carbon tetrachloride to varnish and the constituents of paints is also claimed.—W. P. S.

GERMAN PATENT.

Drying Process, in which the Material to be Dried is Subjected to the Action of Light Rays. A. Junghans. Ger. Pat. 102,606, Sept. 23, 1904. I., page 59.

(B.)—RESINS, VARNISHES.

Copals; Physical and Chemical Properties of —. Bottler. (Cheu. Rev. Fett-u. Harz-Ind., 1906, 13, 1—5.

TABLES are given showing the external appearance, colour, transparency, lustre, fracture, specific gravity, hardness, fusibility, and solubility of fourteen of the principal varieties of commercial copal. The specific gravity of the most valuable varieties lies between 1.03 and 1.07 (estimated without removal of entangled air). If the air be removed, higher numbers are obtained, but the less these differ from the former the greater is the value of the copal. Thus Lindi and Zanzibar copals give numbers differing by only 0.001—0.0015, whilst the (South American) Hymenaea copal and Kauri copal show differences of 0.06—0.064. Relative hardness is an important characteristic for distinguishing copals. A scale of hardness is furnished, beginning with Zanzibar copal (the hardest) and ending with the soft Brazilian varieties. With regard to melting point, the author adopts the temperature at which a fragment in a capillary tube becomes transparent, rather than that of complete liquefaction, since at the latter point decomposition has already commenced. Different varieties exhibit melting points ranging from 90° to 360° C. Besides the older solvents for copal, chlorhydrin, turpeneol, and carbon tetrachloride are employed. Oil of turpentine only dissolves copal when ozonised. An excellent method of dissolving copal consists in drying at 100° C., mixing with sand, treating for 24 hours with dry ether, and then adding an equal volume of warm alcohol. Ether containing $\frac{1}{2}$ of its weight of camphor is another good solvent. A table of solubilities, originally published in Dingler's Polyt. J. (see this J., 1893, 773) is here reproduced with modifications and extensions. Some varieties of copal possess an odour; others are inodorous. Other physical characters, such as refractive index, "streak," &c., are useless as distinctive features.—M. J. S.

Japan Lac [Ki-urushi]. A. Tschirch and A. B. Stevens. Arch. Pharm., 1905, 243, 504—553.

Two authentic specimens of the milky juice of the Japan lac tree, *Rhus vernicifera*, were examined. This lac has the following percentage composition. Soluble in alcohol, 72.4 per cent.; soluble in water, 4.05 per cent.; moisture, 21.20 per cent.; insoluble residue, 2.35 per cent. The portion soluble in alcohol, the urushin or laccic acid of Yoshida, or the laccol of Bertrand, is shown to be a mixture, being separable by light petroleum spirit into two substances, one soluble, the other insoluble. The former is further separable into a non-volatile toxic body, a gum and an enzyme. Lac also contains free acetic acid. The hardening and blackening on exposure to air of the lac, which normally is light yellowish-grey, and of the consistence of a balsam, is due to the action of the oxydase, laccase, on the resins. The lac, spread on wood and covered with a damp paper, soon becomes nearly black and hardens in 24 hours. If it be first sterilised by heat, it does not alter when thus exposed. If sterilised, and then treated with alkali, it blackens at once, but does not harden.

The authors have named the unoxidised resin *urushin*, the oxidation product *oxyurushin*. On treating the lac with alcohol *in vacuo*, the soluble portion, on removal of the solvent, gave to other a body, which, when shaken

out and treated with various alkalis, removed a resin which ultimately changed, in all cases, to oxurushin. Fractional precipitation with lead acetate gave no definite results.

Both urushin and oxurushin contain nitrogen, the latter giving analytical figures corresponding to the formula $C_{102}H_{128}N_2O_{10}$. This is the first recorded instance of the occurrence of a nitrogenous substance among the resins. Neither urushin nor oxurushin have a true acid function. It is remarkable that although lac is so readily oxidised, oxurushin, the oxidation product, is extremely stable and resistant to reagents.

The poison of lac is a non-volatile body, and neither a poisonous gas or a volatile substance as stated by some investigators. It has not been isolated in a pure state, but as an oily liquid. Its action is intense; a very minute particle coming into contact with the skin causes great irritation and inflammation. It resembles toxicodendrol, the toxic substance isolated by Pfaff from *Rhus toxicodendron* and is closely allied to cardol, from *Anacardium* seeds; it has been named "*verniciferol*." It appears to be strictly local in its action on the epidermis. It is intimately combined with the resin, which adheres with remarkable persistence to any article with which it comes in contact, so that in handling lac, the hands should be well protected, and any lac coming in contact with the skin should be at once removed by means of benzene or petroleum. The portion of the lac insoluble in alcohol was found to be chiefly oxurushin.

It was not found possible to separate the gum and enzymic of the lac quantitatively. The gum contains nitrogen, and gives pyrrol on heating with alkali. When hydrolysed it yields serbosa.

The enzyme, resembling the oxidising ferments accompanying other gums, is a gummiase, and has been designated *lac-gummiase*.—J. O. B.

Euphorbium Resin. A. Tschirch and Paul. Arch. Pharm., 1905, 243, 249—291.

EUPHORBIIUM resin contains 0.7 per cent. of a free amorphous resin acid, euphorbinic acid, $(C_{21}H_{36}O)_n$; an aldehyde present in traces only; two resenes, both insoluble in caustic potash, one crystalline, viz., euphorbone, $C_{30}H_{48}O$, to the extent of 40 per cent., the other amorphous, 21 per cent.; also 20 per cent. of water-soluble carbohydrate which differs in character from gum, and 2.5 per cent. of soluble malates, together with an acid principle. The last has not been isolated in a state of purity, it is removed by most solvents, and is very soluble in alcohol. It reduces alkaline cupric tartrate solution, is precipitated by tannin, also by lead salts, and is coloured, and precipitated by ferric chloride.

Euphorbium resin may be identified by the following reaction: 10 grms. are extracted with 10 c.c. of light petroleum spirit. After filtration, the solution is floated on to strong sulphuric acid containing one drop of nitric acid in 20 c.c. A blood-red colour zone is formed at the zone of contact; on shaking, the colour passes into the lower acid layer, and persists for a couple of days, before turning brown.—J. O. B.

Resin Acids of the Coniferae. A. Vesterberg. Ber., 1905, 38, 4125—4132.

WHAT was formerly known as pimaric acid is really a mixture of large quantities of abietic acid with small quantities of true pimaric acid, possibly also with other resin acids. Both *d*- and *l*-pimaric acids give sparingly soluble ammonium salts which crystallise from dilute ammonia in fine needles, whereas the ammonium salt of abietic acid sets to a gelatinous soap. If the pimaric acid be present in considerable proportions, the needles of the ammonium salt separate out soon after cooling, but if the abietic acid be present in predominating quantities, the crystallisation of the ammonium pimarate may not appear for days or even weeks. The author has isolated *d*-pimaric acid from Bordeaux resin (*Pinus Pinaster*). By digesting the resin with 70—80 per cent.

alcohol, a crystalline powder was obtained, consisting mainly of abietic acid; this product when converted into the ammonium salt, yielded practically no crystallisation of the pimarate. But when the pimaric acid had been concentrated by a few recrystallisations from 85 per cent. alcohol (by volume), a good crystallisation of ammonium pimarate was obtained. This was converted first into the sodium salt and then into *d*-pimaric acid, m. pt. 210° — 211° C.—J. F. B.

UNITED STATES PATENT.

Turpentine from Wood; Apparatus for Extracting —. J. G. Gardner, Assignor to Pure White Turpentine Co. Jacksonville, Fla. U.S. Pat. 808,035, Dec. 19, 1905.

THE apparatus consists of a vertical vessel "having a drop-down door provided with a perforated plate, the door and plate being separated to provide a steam chamber." The plate supports the mass of sawdust or ground wood composing the charge, and keeps the same from falling into the outlet provided in the door for the escape of vapours. Means are provided for directing steam downward through the charge and plate, into the outlet, with means for opening up paths for the passage of the steam. —C. S.

FRENCH PATENT.

Resin and Resin Oils; Method of Treating —. K. Bosch. Fr. Pat. 357,391, June 21, 1905. Under Int. Conv., June 21, 1904.

RESIN is distilled in the usual manner until the resin "acids" and pinoline have been driven over. The rate of distillation is then increased so that a clear yellow fraction is obtained amounting to about 60 per cent. of the bulk of the resin taken. This fraction is then heated to boiling, and treated with from 10 to 18 per cent. of sodium hydroxide solution (40° B.). The heating is continued until the resin soap separates from the remaining resin oil. The latter is suitable for use as an insecticide, in paints, &c.—W. P. S.

(C.)—INDIA-RUBBER, Etc.

ENGLISH PATENTS.

Caoutchouc, Gutta-Percha, Balata and the like; Treatment of the Milks or Latexiferous Juices of —. L. P. T. Morisso, Paris. Eng. Pat. 7694, April 11, 1905.

THE object of the invention is to render possible the transport of the latices, from the trees to a distance, without coagulation setting in. This is effected by coating all the surfaces of the trees, with which the latex comes in contact, with an aqueous solution made alkaline with ammonia, and by adding to the vessels in which it is collected, a 10 per cent. alkaline, or "decalfifying" solution (e.g., of potassium oxalate or sodium fluoride). For transport, india-rubber latices are mixed with a solution of an alkali or an alkaline or "decalfifying" salt (e.g., 3 grms. of ammonia per 100 grms. of latex), a solution of phenol or of formaldehyde being also added in the case of *Hevea* latices; gutta-percha or balata latices are mixed with formaldehyde solution, care being taken that the liquid is distinctly alkaline.—E. W. L.

Felt Substance for Industrial Purposes and Method of Manufacturing the same. R. Haddan, London. From A. Ripert, Asnières, France. Eng. Pat. 2974, Feb. 13, 1905.

THE "felt" claimed as a new article of manufacture consists of a mixture of pure india-rubber and entire asbestos fibres, the latter being present in quantities not exceeding 80 per cent. of the weight of the mixture. Pure india-rubber is heated to 206° F., and well mixed with a small quantity of asbestos. The mass is then heated to its melting point (293° F.) and the remainder

of the asbestos added, and the whole well mixed in order to ensure the thorough felting of the mixture. Cotton or silk-waste fibres may also be incorporated with the mixture.—E. W. L.

FRENCH PATENTS.

Hydrocarbons; Transformation of — [into Rubber, &c., Substitutes]. E. A. L. Rouxville. Fr. Pat. 356,716, Aug. 7, 1905.

Liquid or solid hydrocarbons of all kinds, or their derivatives, are oxidised, and the oxidation products separated, purified, coagulated and vulcanised. The resulting compounds are stated to be viscous or solid bodies (according to the original hydrocarbon used). They are employed as substitutes for rubber, insulating materials, in the preparation of varnishes, &c. For example, a rubber substitute is prepared by dissolving 1 part of rosin in 5 parts of turpentine oil, filtering, and treating the solution with 2 parts of sulphuric acid. The portion of the product which is liquid after standing, is boiled with excess of water, and the mixture neutralised with alkali. The product is filtered off, washed, again boiled with water, collected and treated with sulphur chloride. The resulting body is stated to closely resemble ordinary gutta-percha.—T. F. B.

Rubber Waste of all kinds; Process for the Regeneration of — J. Neilson. Fr. Pat. 357,336, Aug. 29, 1905.

THE waste vulcanised rubber is dissolved in rosin oil (b. pt. 300°–390° C.), and the caoutchouc is precipitated from the solution by a ketone, for example, acetone.—A. S.

XIV.—TANNING, LEATHER, GLUE, SIZE.

(Continued from page 33.)

Kamatchil Bark. J. Paessler. Deutsche Gerh.-Zeit., 1905, 139–140.

THIS newly imported tanning material from Saypan (Ladron or Marianne Islands) was submitted to the author for valuation. An analysis gave the following results:—Tannins absorbed by hide, 29.3; Non-tannins, 5.6; Insoluble in water at 15° C., 52.1; and Water, 13.0 per cent. The material contained 0.2 per cent. of dextrose and 0.4 per cent. of sucrose. 23.0 per cent. of the tannins are easily soluble and the bark therefore compares favourably with oak- and pine-bark, but as it contains much less non-tannins than these, it should be used for tanning in combination with one of them. The new tanning material imparts to the leather a very pale colour which darkens somewhat on exposure to light and air. Judging from the results obtained by practical experiments in tanning calf-skins for russet-calf and hides for light sole-leather (Vachelador), the author thinks that Kamatchil-bark should become as popular as mallet-bark has, and he draws special attention to its remarkable weight-giving properties.—F. K. K.

UNITED STATES PATENTS.

Tanning Vat. R. Koenitzer, St. Louis, Mo. U.S. Pat. 800,899, Dec. 12, 1905.

THE hides or skins are suspended from shafts mounted in a frame on the top of the vat containing the tanning solution, these shafts being so operated that when they are rotated, the hides are successively "rolled and unrolled out of the tanning solution."—A. S.

Hides; Apparatus for [Electrically] Treating — F. B. Hinkson, Newcastle, Pa., Assignor to J. M. and J. J. Flannery, Pittsburg, Pa. U.S. Pat. 807,980, Dec. 19, 1905.

THE apparatus consists of a tank furnished with bars, from which the hides are supported within the tank. A number of pairs of electrodes are also arranged in the tank, parallel to the bars, the electrodes of the same polarity being connected in multiple. Means are pro-

vided for reversing the direction of the electric current passing through the electrodes.—A. S.

FRENCH PATENTS.

Tanning; Method of — E. E. Guignan and L. E. E. Defaix. Fr. Pat. 350,242, Oct. 20, 1904.

ACCORDING to this patent, hides are soaked in a solution of sodium carbonate of 10° B. for three to six hours. After washing with water they are allowed to remain for five hours in a bath of caustic soda the strength of which may vary from 2° to 30° B. From this they are transferred to a bath of hydrochloric acid (1° to 5° B.) in which they remain for two hours. Finally the hides are washed and the "beam-work" finished in the usual way. The tannage consists of a special bath of sodium or ammonium sulphorincolate (2 to 30 per cent.) and sumach extract, or similar tanning material (2 to 50 per cent.). The strength of this bath is gradually raised from 4° B. to 30° or 40° B.—W. B. H.

Leather; Process for Making — Tough and Impervious. F. W. Stoffer. Fr. Pat. 357,037, July 25, 1905.

LEATHER is impregnated with a solution of 1 part of caoutchouc or gutta-percha in 16 parts of benzene or other solvent, to which is added 10 parts of linseed oil. Wax and resin may be added to thicken the solution.—W. B. H.

Leather; Oil for the Preservation of — L. Vulted, née Maler. Fr. Pat. 356,936, August 16, 1905.

CLAIM is made for an oil which will penetrate either dry or wet leather, and will make it thoroughly impervious to water. The oil is applied cold and consists of poppy-seed (*Papaver somniferum*) oil, 45 grms.; sesame (*Sesamum orientale indicum*) oil, 45 grms.; oil from the fruit of *Eriobotrya japonica* (a kind of Japanese medlar), 10 grms.—W. B. H.

Glue; Method of Purifying — W. S. Sadikoff. Fr. Pat. 356,849, July 17, 1905.

GLUE is soaked in cold water and dissolved in a hot 25 per cent. solution of magnesium sulphate. The hot solution is filtered, and to the filtrate is added a 25 per cent. solution of magnesium sulphate containing 0.5 per cent. of hydrochloric acid (or, if necessary, sulphuric acid). A white flocculent precipitate is obtained which is difficult to filter. The remainder of the glue in the saline solution is extracted by treatment with magnesium sulphate.

The viscous matter is washed, then dissolved in hot water, and allowed to cool, a quantity of weak alcohol acidulated by 1 per cent. of hydrochloric acid being added just before the mass solidifies. From 2 to 3 parts by volume of strong alcohol (methyl or ethyl) are then added and the solution filtered, charcoal being used if necessary. The glue is finally precipitated from this solution by neutralising with ammonia and washing with alcohol or water.—W. B. H.

XV.—MANURES, Etc.

(Continued from page 34.)

Manganese as a Fertiliser. G. Bertrand. Comptes rend., 1905, 141, 1255–1257.

THE discovery of the presence of manganese in laccaes led to experiments on the employment of salts of this metal in fertilisers. It was found on the small scale that very appreciable results were obtainable with the use of an extremely minute proportion of manganese. This observation was satisfactory from the point of view of expense, but, seeing that most arable soils already contain notable quantities of manganese, it raised a doubt whether the addition of further small proportions could give any beneficial effect. The author has conducted field experiments with oats on a soil which contained 0.057 per cent. of manganese, including 0.024 per cent. soluble in boiling 1 per cent. acetic acid. Two plots of ground received the usual fertilisers in the same proportions, and to one of them manganese sulphate, at the rate of 50 kilos. of dry

salt per hectare = 1.6 grm. of metal per sq. metre, was added. The results were extremely satisfactory and showed an increase in the total crop of 22.5 per cent. in favour of the plot to which manganese was added. This increase was made up of 17.4 per cent. increased yield of grain and 26.0 per cent. increase of straw. The analysis showed that the grain from the plot, which received the manganese, had a higher bushel-weight and contained less moisture and slightly less nitrogen than the grain from the control plot.—J. F. B.

Fertilisers in Japan. Bd. of Trade J., Jan. 4, 1906.

IN 1904, the imports of fertilisers, which had been growing steadily for some years, showed a slight diminution, owing to disorganisation caused by the war. During the first six months of 1905, however, the value of the fertilisers imported amounted to 12,976,352 yen, as compared with 5,757,075 yen in 1904. The increase was shown chiefly in oilcakes (7,245,109 yen, as compared with 2,035,279 yen); this remarkable increase was due to the resumption of commercial relations with Nanchang, the chief centre for the export of oilcakes. A large increase is also shown in the imports of ammonium sulphate (638,217 yen), calcium phosphate (1,179,304 yen), and sodium nitrate (636,997 yen); these, with oilcakes, being the fertilisers most in demand. A very large proportion of this trade goes to Kobe, which takes six-sevenths of the oilcakes, two-thirds of the phosphate and sulphate, and one-half of the nitrates. China furnishes all the oilcakes imported; one-third of the nitrates are imported from the United States, and the remainder from Chile and various other countries; nearly the whole of the import of calcium phosphate and ammonium sulphate comes from the United Kingdom. There are a certain number of chemical factories at Osaka which produce fertilisers, more especially ammonium sulphate. [T.R.]

XVI.—SUGAR, STARCH, GUM, Etc.

(Continued from page 34.)

Sugar Production of Argentina. Bd. of Trade J., Dec. 28, 1905.

THE production of cane sugar in the Argentine Republic in the year ending Oct. 31, 1905, amounted to 129,043 metric tons; in the same period of 1903—1904, it amounted to 124,763 tons, an increase of 4280 tons in 1905. There are 37 sugar factories in operation, and one refinery in Rosario. The industry is very prosperous at present, and prices have not varied much in spite of the larger production, owing, presumably, to larger consumption in the country. The better-managed factories with modern machinery are paying good dividends, assisted by the very high import duty on sugar. [T.R.]

XVII.—BREWING, WINES, SPIRITS, Etc.

(Continued from page 36.)

Barley and Green Malt; Influence of Light on Germinating —. G. Bode. Woch. f. Brau., 1905, 22, 768—770.

MANY maltsters have observed that blue light has a favourable influence on the germination process, and they therefore cover the windows of their maltings with a blue wash. At the same time it must be admitted that the influence of light in the malting process must be very small compared with that of other conditions such as temperature and moisture, since pneumatic malting is conducted perfectly well in the dark. The rays of the blue half of the spectrum do, however, appear to stimulate the mobility of the protoplasm and to increase the vital activities of the corn. The rays of the red half of the spectrum are favourable to chlorophyll assimilation, but, since the grain in the malting stage develops quite independently of such assimilation, these rays may be excluded without harm. It is important, however, that the germinating grain should be protected from direct sunlight. The blue and ultra-violet rays are known to have a destructive action upon diastase. This action, however, is mitigated on the one hand by the natural protection afforded by the yellow colouring matter of the husk and by the fact that the total amount of light admitted to the malting floor is never very great, and on the other hand by the circumstance that the brewer always works with an excess of diastase over his actual requirements. For the preparation of highly diastatic malt for distilling purposes, however, it might be advantageous to work entirely in the dark or behind windows of yellow glass.—J. F. B.

Starch Paste; Certain Liquefying and Saccharifying Actions on —. P. Petit. Comptes rend., 1905, 141, 1247—1249.

MALT infusions react towards guaiacum tincture like solutions of ferrous and ferric or manganous and manganic compounds. The presence of iron can easily be detected in the coagulum from the boiled infusion; manganese is also present in minute traces. The ferric compounds can be reduced by treating the infusion with caustic soda and aluminium; after neutralisation of the alkali by acetic acid, the liquid does not give a blue reaction with guaiacum and is devoid of liquefying and saccharifying properties. Conversely, if a malt infusion gives, in the natural state, only a very faint guaiacum reaction, it may be made to give a full reaction by adding a trace of alkali, passing a current of air through the liquid and re-acidifying with lactic acid. The liquid, after such treatment, is still capable of liquefying starch, but has lost its saccharifying property. Citric acid destroys the property of liquefying starch and of reacting with guaiacum. Solutions possessing some of the properties of malt infusions can be made artificially by treating a solution of commercial albumin with ferrous and ferric oxides. The filtered solution gives a blue reaction with guaiacum and has a pronounced liquefying action on starch paste at 20° C. The addition

of lactic acid and asparagine to the albumin solution containing the oxides of iron intensifies the starch-liquefying action very considerably, and even imparts a distinct saccharifying power to the liquids.—J. F. B.

Fermentative Enzymes from Plants; Isolation of — J. Stoklasa. *Centralb. Bakt.* [Abth. 2], 1904, 12, 86; through *Z. ges. Brauw.*, 1905, 23, 860.

THE author sums up the conclusions drawn from his various researches on anaërobic respiration in plants (see this J., 1905, 907 and 204). It is definitely established that the process of anaërobic respiration in the plant cell is an alcoholic fermentation accompanied by the production of lactic acid, the mechanism of the process being governed by the nature of the available carbohydrates. The anaërobic metabolism of plants is identical with fermentation by yeast, and its quantitative relationships are the same. Aerobic respiration is probably a secondary phenomenon; the primary process is the intra-molecular movement of the atoms in the molecule of living matter involving the migration of oxygen in the molecule. In absence of air, the reduced atomic grouping—i.e., alcohol—has no opportunity of becoming fixed with the absorption of oxygen in molecular syntheses; it is therefore eliminated together with carbon dioxide. But in presence of air such fixation occurs under the influence of aëro-oxylases and the alcohol takes part in the building up of new portions of living protoplasm, in which process carbon dioxide and hydrogen are not formed.

The migration of atoms in the molecule of dextrose is termed "glycolysis," a process which is induced by glycolytic enzymes; first by an enzyme "alcoholase," and secondly by one called "lactolase," which produces lactic acid.—J. F. B.

Yeast; Action of Stimulants on — Delhrick. *Tageszeit. f. Brau.*, 1905, No. 242.

CERTAIN substances, especially the salts of phosphoric acid, asparagine, peptone, magnesium sulphate, &c., stimulate the fermentative power of yeast in a most marked degree. The stimulating influence of the addition of cereal grist is to be ascribed to the presence of such bodies in the corn. Oat grist shows the strongest zymase-producing power, owing probably to the phosphates contained therein. Certain industrial effluents, such as the water used for washing the yeast, also increase the zymatic power and fermentative activity. The metabolic products of yeast isolated by Kutcher also belong to the category of yeast stimulants. (See this J., 1905, 555 and 1120.)—J. F. B.

Beer; Fixation of Carbon Dioxide and Permanence of "Head" in — Mohr. *Tageszeit. f. Bran.*, 1905, No. 242.

THE fact that beer is capable of retaining a larger proportion of carbon dioxide than an equivalent mixture of water and alcohol is attributed to physical causes rather than to chemical. The main factor is the viscosity of the liquid, which increases the stability of the super-saturated solution. The viscosity is due to the colloids which hold the carbon dioxide in solution by a kind of surface action termed "adsorption." The "head" of foam also offers a resistance to the escape of the carbon dioxide remaining in the beer. The existence of the "head" is again mainly due to the colloids, but the hop resins also play a part. The carbohydrates have no appreciable influence.—J. F. B.

Tannin in Wine; Determination of — L. Krámský. *XXIII.*, page 93.

ENGLISH PATENTS.

Yeast; Dedicating and Preserving — H. Livingstone, London. Eng. Pat. 27,026, Dec. 17, 1904.

CLAIM is made for the method of dedicating and preserving yeast consisting in removing the bulk of the liquid therefrom, dividing or crumbling the moist yeast, spreading the latter out thinly, subjecting it to a current of pure air,

naturally dry or artificially dried, of a temperature not exceeding about 70° F., and packing the dried yeast in tins or other receptacles in a vacuum.—T. H. P.

Caramel; Preparation of — and its Application as a Colouring Matter in the Production of Fermented Liquors and for other Industrial Purposes. T. D. Lichtenstein, London. Eng. Pat. 28,547A., Dec. 28, 1904.

CLAIMS are made for (1) the process of purifying caramel by subjecting its solution to dialysis, with or without subsequent concentration; (2) the products thus obtained and beverages coloured by them; (3) the colouring of beer by adding dialysed caramel to the unfermented wort.—T. H. P.

Beer and Similar Beverages; Cooling and Aerating — M. F. Chambers and D. S. L. Archibald, Romford. Eng. Pat. 2317, Feb. 6, 1905.

THE apparatus described, in which the cooling and aeration of beer and the like beverages are carried out simultaneously, consists of a suitable aerating vessel provided with a cooling coil the ends of which pass through stuffing-boxes in the aerator into inlet and outlet pipes from the brine or other cooling medium. The cooling coil is fitted with beaters or wings to act as rousers, and is rotated by means of a pulley fitted to one of its prolonged ends outside the aerator, or by other means. The two ends of the coil may be connected together inside the aerator by a central hollow or solid shaft, so as to provide for the symmetrical rotation of the coil within the aerator.—T. H. P.

Beer and other like Liquids; Process for Conditioning, Cooling and Freezing from Fermentable Matter — E. H. West and R. W. Webster, London. Eng. Pat. 5360, March 14, 1905.

CLAIM is made for an improved process for conditioning beer and other like liquids, which consists in running the beer or other liquid into a vessel provided with devices for warming, cooling, and, when necessary, agitating the same, adding thereto dry hops, and, when necessary, "priming" or unfermented wort. The mixture is then heated by means of a warm liquid applied to the surface of the said vessel in order to facilitate fermentation, with or without rousing by devices operating in the vessel. When the desired point of conditioning is reached, the fermentation is checked by cooling the mixture to a temperature approximating to its freezing point, by means of a cold liquid applied to the surface of the vessel.—T. H. P.

Whisky and the like; Method and Means of Blending — J. Dunbar, Glasgow. Eng. Pat. 1355, Jan. 24, 1905.

CLAIMS are made for: (1) the blending and complete mixing of various kinds of manufactured whisky or other liquid substances by the use of a circlet of inwardly directed pipes associated with an air pipe so as to form a fine spray which is collected in a confined space; (2) the continuous circulation, aeration and cooling of the drinking water in the tanks on board sea-going vessels, by this spraying process, and the cooling of manufactured beer in heated atmospheres.—T. H. P.

GERMAN PATENT.

Beverages free from Alcohol or Poor in Alcohol; Process for the Preparation of — from Sterile Fermented or Non-fermented Fruit Juices and the like. C. Brünneke. Ger. Pat. 162,486, Dec. 9, 1903.

THE claim is for a process of preparing beverages free from alcohol or poor in alcohol from fermented or non-fermented fruit juices, by the action of *Saccharomyces membranaefaciens* or *Mycoderma cerevisiae* with free access of sterilised air. The fruit juices is sterilised in a vessel, the outlet of which is closed by an air-filter, and a pure culture of *Sacch. membranaefaciens* or *Mycoderma cerevisiae* is introduced. After a few days, the decomposition of the alcohol or sugar becomes perceptible. The fermentation can be stopped at any time desired by heating to at least 60° C.—A. B.

Drying Vegetables, Fruits, Starch and the like; Apparatus for — N. Yagn, St. Petersburg. Eng. Pat. 5225, March 13, 1905.

A TALL chamber is divided into a series of horizontal compartments by V-shaped metal partitions. The lowest compartment is heated by steam and is in communication with the atmosphere, whilst the second and succeeding chambers are heated by conduction through the metal divisions to a successively decreasing degree and are isolated from the external air by flaps or doors which cover the openings through which the material to be dried is introduced or withdrawn. The latter is spread on trays which are introduced at short intervals into one end of the second compartment and pushed forward to the other end, when they are lifted to the next higher compartment and so on till the top compartment, which is open to the air, is reached. The air in each compartment is agitated by fans, and being heated by contact with the metal partition forming the bottom of the compartment, rises through the material in the trays and takes up moisture; it is next cooled by contact with the underside of the bottom of the compartment above, deposits the moisture on the surface and sinks, to perform the cycle over again. The deposited moisture flows down the under surface of the V-shaped partitions and is carried away by a gutter.—W. H. C.

UNITED STATES PATENTS.

Liquids; [Electrical] Apparatus for Sterilising, Purifying and Ageing — R. C. Turner, Assignor to C. E. Turner, Columbus, Ohio. U.S. Pat. Re-issue 12,421, Dec. 12, 1905.

THE liquid is allowed to flow from a tank into a funnel supported above a receiving vessel. In the latter is placed an electrode connected with one pole of a battery or electric supply, whilst the funnel is connected with the other pole. The current passes from the vessel to the funnel through the stream of liquid falling from the stem of the funnel. The receiving vessel is provided

with a spout so that the liquid may flow into a second funnel and receiving vessel placed below the first pair and similarly connected with an electric supply.—W. F. S.

Milk Separator; Centrifugal — B. A. O. Proffius, Assignor to Aktieselskabet Burmeister & Wains Maskin-og Skibsbyggeri, Copenhagen. U.S. Pat. 807,639, Dec. 19, 1905.

SEE Eng. Pat. 14,960 of 1904; this J., 1905, 509.—T. F. B.

FRENCH PATENT.

Alimentary Product from Grains; Preparation of — Blattmann and Co. Fr. Pat. 357,451, Sept. 2, 1905.

THE substance extracted from cereals, &c., by alcohol, mixtures of alcohol and ether, benzene, carbon tetrachloride or chloroform is separated from the solvent by evaporation, and the residue obtained treated with acetone or methyl acetate. The product is then dried at a temperature below 40° C.—W. P. S.

(B.)—SANITATION; WATER PURIFICATION.

Plumbism due to Electrolysis. B. Latham. Electrician, 1905, 56 [10], 398—399.

A CASE of lead poisoning having occurred in a cottage supplied with water by the South Hants Waterworks Co., investigations were carried out for the purpose of ascertaining the cause of the presence of notable quantities of lead in the water. The corrosion of the service pipe was found to be entirely due to electrolysis, set up by leakage from electric lighting mains and installation, in the near vicinity. When a current of 30 amperes was passing through the mains an E.M.F. of 1.8 volts was detected between the earth-return and the water pipe running to the house, which, in the engineer's opinion, accounted for the whole trouble which had occurred. Laboratory experiments confirmed this view.—W. P. S.

ENGLISH PATENT.

Sewage Sludge; Method and Apparatus for Recovering Fatty and Oily Matter from — The Mayor, Aldermen and Citizens of Bradford, J. Garfield, Bradford, and J. Groseman, Manchester. Eng. Pat. 29,558, Dec. 31, 1904.

THE sewage sludge is treated with sulphuric acid, or with alkali, or heated under pressure so as to liberate the fatty acids. The mass is then filter-pressed and the cake, now containing about 30 per cent. of water, distilled. For this purpose it is fed by means of a double hopper into long D-shaped retorts which are surrounded with tiles and saddles. A travelling arrangement conveys the cake through the retorts at such a rate that when it reaches the other end of the retorts, the fatty acids, ammonia and other organic compounds are removed, the heat being kept sufficiently low to enable the residue to retain such an amount of nitrogenous matter as will render it available for manurial purposes. The gases leaving the retorts are condensed, scrubbed and separated, whilst the residue is drawn off through a closed discharging box. Superheated steam may be blown through the retorts during the distillation. The temperature to which the retorts are heated depends on the nature of the sludge.—W. F. S.

UNITED STATES PATENTS.

Fuel; Artificial — [from Garbage]. E. C. May, Assignor to National Garbage Fuel Co., U.S. Pat. 807,629, Dec. 19, 1905. II., page 61.

Water; Process for Purifying — J. F. Wixford, St. Louis, Mo. U.S. Pat. 807,008, Dec. 12, 1905.

FROM 4 to 8 grains of ferrous sulphate are added to each gallon of water and afterwards sufficient calcium hydroxide to neutralise the free carbon dioxide and sulphates in the water. The reagents are added in solution to a running stream of the water, the lime solution being introduced at a point below that at which the ferrous sulphate is

added. After the addition of the reagents the water is kept in a state of agitation for a few minutes and then allowed to settle. The quantity of calcium hydroxide added should be such that the water shows a distinct alkalinity when tested with silver nitrate after the lapse of a considerable time.—W. P. S.

Water; Process for Purifying — J. F. Wixford, St. Louis, Mo. U.S. Pat. 807,412, Dec. 12, 1905.

THE process consists in adding from 0.25 to 2 grains of ferrous fluoride to each gallon of the water and afterwards sufficient calcium hydroxide solution to render the water distinctly alkaline. After mixing, the water is allowed to settle.—W. P. S.

Purification of Liquids; Method of Biological — W. P. Dunbar, Hamburg, Germany. U.S. Pat. 807,667, Dec. 19, 1905.

SEE Fr. Pat. 337,301 of 1903; this J., 1904, 500.—T. F. B.

GERMAN PATENT.

Argillaceous Matter from Waters; Process for the Separation of — C. Borchardt. Ger. Pat. 162,698, May 5, 1903.

THE process is intended for the separation of argillaceous matter from water which is to be subsequently treated in contact-beds or filters. A long piece of textile material is laid over the perforated bottom of the supply channel of the filter-chamber and is held in place by weights on the two long sides, and also by the water. The sides of the bottom of the supply channel are preferably constructed in the form of steps on which the weights holding the cloth in position are placed; the width of cloth used may then be varied according to the quantity of argillaceous matter contained in the water. It is stated that by the use of this auxiliary filter for argillaceous matter, the working life of a filter-chamber or bed is lengthened by from one to three months.—A. S.

(C.)—DISINFECTANTS.

ENGLISH PATENT.

Insecticide; Improved — as a Destructive Agent for Farm and Garden Invertebrate Pests. E. M. Holmes, Sevenoaks, Kent. Eng. Pat. 8081, April 15, 1905.

CLAIM is made for an insecticide consisting of saponin mixed either as a solution, emulsifier or powder with stearic oil, tar oils, fatty oils, preparations of tobacco, sulphur, lime, hellebore, quassia and flowers of chrysanthemum, or any of them, whereby certain of the said substances are rendered more suitable for practicable application as insecticides and their efficiency increased.—T. H. P.

FRENCH PATENTS.

Resin and Resin Oils; Method of Treating — K. Bosch. Fr. Pat. 357,391, June 21, 1905. XIII B., page 82.

Insecticide; Manufacture of an — K. Bosch. Fr. Pat. 357,392, June 21, 1905. Under Int. Conv., June 21, 1904.

THE preparation is particularly applicable for the destruction of phylloxera, caterpillars, &c., and consists of nitrophenol or a solution of the same. Resin soap may be added to bring the solution in close contact with the leaves, and for transport the preparation may be mixed in the form of a powder with infusorial earth, gypsum, barites, &c. Sulphur and copper sulphate may also be added.—W. P. S.

Copper and Calcium; Manufacture of a Double Acetate of — [Insecticide]. I. C. Pontius. Fr. Pat. 357,414, Aug. 31, 1905.

A BOILING concentrated solution of copper sulphate is added to a hot concentrated solution of calcium acetate, until the colour of the solution becomes blue without a green tinge. The acetic acid vapour expelled during the

process is conducted away for condensation. The solution, filtered from the precipitated calcium sulphate, is set to crystallize. The composition assigned to the crystals formed, is $6(C_2H_3O_2)_2Ca$, $6(C_2H_3O_2)_2Cu$, H_2O , and the salt is said to be very efficacious in the treatment of infected vines.—E. F.

XIX.—PAPER, PASTEBQARD, Etc.

(Continued from page 38.)

ENGLISH PATENTS.

Paper; Manufacture of Irregularly Coloured — O. Imray, London. From Farbwerke vorm. Meister, Lucius und Brüning, Höchst a/ Main, Germany. Eng. Pat. 27,870, Dec. 30, 1904.

A SUITABLE solution of dyestuff is allowed to drop from a series of vessels on to the pulp in a paper machine at a suitable point, where the pulp is sufficiently dilute, i.e., between the admission box, above the breast roller, and the sluices. The vessels containing the colour solution may be given a transversal movement in relation to that of the paper pulp, or an undulating movement may be given to the pulp by placing weirs before the last sluice, or by suitably adjusting the flow of water to the pulp.—T. F. B.

Paper-Making Machines; Apparatus for Supplying Colouring Matter, Mixed Colour Solutions, or Colour Producing Chemicals in — for the Manufacture of One Side Coloured, Clouded Coloured and Marbled Papers. C. Tittel, Josefthal, Austria. Eng. Pat. 17,163, Aug. 24, 1905.

THE apparatus shown in side elevation in the accompanying figure is suited for the production of "marbled" or "clouded" coloured papers. The colour solution is introduced through pipe c, and enters pipe e, regulated by aid of the dial a; inside pipe e is a perforated steam pipe r₁, both these pipes extending the width of the web of paper. On the top of e are provided a number of nozzles (see z), through which the colour solution is forced by the steam. These nozzles terminate above the trough f, and cause the colour to flow over it in irregular streams, whence it passes over the squeezing roller b on to the web of paper. For preparing evenly coloured paper, pipes e and r are replaced by stirring blades, revolving at about 800 revolutions per minute. These also serve to drive the colour through a number of holes in the cover b, whence it flows through sluice g (controlled by wheel s) on to the squeezing roller as before. The above is an improvement on Eng. Pat. 16,796 of 1904 (this J. 1904, 334).—T. F. B.

UNITED STATES PATENTS.

Card or Pulp Board; Method and Apparatus for the Manufacture of — H. D. Loria, Orchamps, France.
U.S. Pat. 807,753, Dec. 19, 1905.

See Eng. Pat. 23,245 of 1904; this J., 1905, 149.—T. F. B.

Wood-Fibre Digester. A. W. Handford, Evanston, Ill., Assignor to Wood Distillates and Fibro Co., Chicago.
U.S. Pat. 807,925, Dec. 19, 1905.

THE apparatus consists of a rotary shell containing a rotary axial shaft fitted with arms for the purpose of moving forward the contents of the shell while the latter is at rest. The shaft and shell can be rotated separately, and either of them can be disconnected from the source of power. Steam is supplied to the shell through a pipe telescoping with the axial bore of the shaft, which bore opens into the shell, whilst an exhaust pipe is connected with the opposite end of the shaft bore. A number of pipes, connected with the shaft bore, extend longitudinally in the shell, and open at different points to distribute steam. A valve connection for a drain pipe is provided at one part of the shell, and a drain pipe, fitted with a pump, is provided to connect with this valve when the shell is in a certain position. The exhauster is connected with the exhaust-pipe to draw off vapours from the shell. The shell is also fitted with a manhole.—C. S.

Pulp and Paper Machinery. H. Parker, Assignor to Improved Paper Machinery Co., both of Nashua, N. H.
U.S. Pat. 808,614, Dec. 26, 1905.

In a paper machine of the cylindrical type, each independent "cylinder mold" is provided with its own couch roll and endless felt. The webs made on each cylinder are superposed to form one composite web of paper which passes over a suction apparatus above which a press-roll is adjusted so as to subject the web simultaneously to pressure and suction.—I. F. B.

FRENCH PATENTS.

Photographic Papers for Producing Images Sensitive to Daylight; Phosphorescent — R. Bau. Fr. Pat. 350,735, Aug. 7, 1905. XXI., page 90.

Straw, Jute, &c. Treatment of — [for Paper Manufacture]. D. Gaj-Tenna. Fr. Pat. 357,374, Aug. 31, 1905.
Under Int. Conv., March 27, 1905.

In order to obtain a tough cellulose from straw, jute, esparto, &c., suitable for use in paper manufacture in place of wood pulp, the following process is carried out: 100 kilos. of the straw, &c., are boiled with a mixture of sodium carbonate, 8 to 10 kilos.; lime, 6 to 7-5 kilos.; borax, 0-5 to 1 kilo.; kaolin or clay, 2 to 2-5 kilos.; and casein or starch, 1 to 1-5 kilos. The product is washed, bleached, and made up into paper in the usual way. It is stated that the yield of bleached cellulose is from 53 to 58 per cent. of the weight of straw used.—T. F. B.

Silk; Recovery of Solvents, especially Alcohol and Ether, from Bobbins of Artificial — J. Douge. Fr. Pat. 350,835, April 21, 1905. V., page 71.

Viscose; Process of Making Threads and Films of — S. Pissarev. Fr. Pat. 357,050, Aug. 19, 1905. V., page 70.

Cellulose Solutions; Process of Making — by means of Alkylamines. E. W. Friedrich. Fr. Pat. 357,171, Aug. 24, 1905. Under Int. Conv., Aug. 25, 1904.

It is proposed to employ solutions of copper oxide in alkylamines instead of in ammonia for dissolving cellulose for various purposes, e.g., making artificial silk. 320 grms. of cellulose are moistened with hot water, and added to 3-4 litres of caustic soda solution (30° B.); 250 grms. of copper sulphate are then gradually added, the solution of sodium sulphate is filtered off, and the cellulose is dissolved in a 33 per cent. aqueous solution of methylamine, the temperature being kept low. These solutions are stated to coagulate very rapidly, the resulting threads being very elastic.—T. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

(Continued from page 39).

Strychnine; Action of Bromine on — H. Beckurts. Arch. Pharm., 1905, 243, 493-496.

It has been previously shown that when two atoms of bromine are allowed to act on strychnine hydrobromide in aqueous solution, bromo-strychnine hydrobromide $C_{21}H_{21}Br_2N_2O_2 \cdot HBr$ is formed. With four atoms of bromine, another bromo-compound, bromostrychnine dibromide, $C_{21}H_{21}Br_4N_2O_2$ is obtained as well, in the form of a bulky yellow precipitate. On employing an excess of bromine, this dibromide is not obtained, but the tribromide $C_{21}H_{21}Br_3N_2O_2$ results.

This tribromide is obtained by the addition of an excess of bromine solution to a strong hot solution of strychnine hydrobromide until precipitation ceases, and the supernatant liquid is coloured yellowish-red. The micro-crystalline tribromide, dried over sulphuric acid, has no definite m. pt.; it is insoluble in water, and sparingly soluble in alcohol; the latter solution is at first alkaline in reaction but becomes acid on keeping. When strychnine nitrate is used, the precipitate obtained is not pure; bromostrychnine tribromide is not obtained, but a precipitate containing less bromine and much nitric acid.

On treating bromostrychnine tribromide with boiling absolute alcohol, the yellow alkaline solution at first obtained became colourless and acid on continued heating for 10 minutes. On evaporation, no crystalline compound was formed; the syrupy residue obtained was dissolved in hot water, and treated with excess of ammonia. The precipitated body was dissolved in alcohol; on adding water to this solution, crumbling crystals were obtained, which, when recrystallised, separated as well formed rhombic tablets of monobromostrychnine $C_{21}H_{21}BrN_2O_2$; m. pt. 222° C. The same body was obtained by the action of alcoholic potash. With hydrogen sulphide, monobromostrychnine hydrobromide was formed, and nascent hydrogen reduced the tribromide to the monobromide.

When heated at 105° C., to constant weight, the lighter coloured powder had the constitution of bromostrychnine dihydromide $C_{21}H_{21}BrN_2O_2 \cdot Br_2$. This dihydromide behaves like the tribromide when treated with alcoholic potash, hydrogen sulphide and nascent hydrogen. It may also be obtained by extracting the tribromide with cold alcohol which removes one atom of bromine.

The behaviour of bromostrychnine tribromide indicates that the bromine atoms are readily split off, so that it must be regarded as a more bromo-additive compound of bromostrychnine and bromine.—J. O. B.

Otto of Rose; Alcohol in — W. H. Simmons. Chem. and Druggist, 1906, 68, 20.

THE presence of dilute alcohol, has, in two cases, recently been detected in deliveries of otto of rose; the preliminary samples did not contain alcohol, the presence of which was probably due to insufficient drainage after the vases had been cleaned and rinsed with alcohol. The quantity of foreign matter (alcohol plus water) found was 0-65 and 1-0 per cent. The refractive indices of the oils were low, otherwise their properties were those of the pure oil.
—T. F. B.

Oil of False Savin (Juniperus Phœnicia). J. C. Umney and C. T. Bennett. Pharm. J., 1905, 75, 827-829.

THE authors recently examined a sample of savin oil from the South of France, the characters of which differed considerably from those of pure savin oil and German savin oil, but agreed closely with those of some of the oils which, hitherto, have been looked upon as adulterated with oil of turpentine. Examination of the plant from which the oil was derived showed this to be not *Juniperus sabina* but *Juniperus Phœnicia* (the common Mediterranean species). A comparison of the oil of *Juniperus Phœnicia* with German savin oil and with oil distilled in England from *Juniperus sabina* is given in the following table:—

	Koglich. From <i>J. Sabina.</i>	German. From <i>J. Sabina.</i>	French. From <i>J. Phœnicia.</i>
Specific gravity	0.909	0.920	0.892
Optical rotation	+ 68°	+ 42°	+ 4°30'
Esters	47.6%	30.5%	9.3%
Total sabinol	52.1%	48.2%	17.1%
Solubility in 90% alcohol	1 in 1	1 in 1	1 in 5
Portion distilling—			
Below 155° C.	nil	nil	18%
Below 165° C.	nil	nil	61%
Below 175° C.	14%	nil	68%
Below 180° C.	29%	4%	80%
Below 200° C.	48%	29%	82%
Below 220° C.	62%	49%	84%
Below 230° C.	80%	60%	86%

The oil from *J. Phœnicia* contains over 75 per cent. of pinene.

The authors point out that as the medicinal properties of sabin oil are most probably due to the sabinol and its acetate present therein, the oil from *J. Phœnicia* (false sabin) should not be substituted for the oil from *J. sabina* (true sabin).—A. S.

Parsley Fruits; Essential Oil of —. [Proportions of "Light" and "Heavy" Oil]. Haensel's Report. Oct., 1905, 26.

THURINGIAN parsley seeds have been found to yield 1.1 per cent. of "light" oil and 3.5 per cent. of "heavy" oil. The "light" oil had the sp. gr. 0.887 at 18° C.; $d_{20}^{20} = -45^\circ$. The "heavy" oil the sp. gr. 1.106 at 18° C.; $d_{20}^{20} = -1^\circ 25'$. No crystallisation of apinol was observed either during distillation, or on standing.—J. O. B.

Cinnamon Chips; Essential Oil of —. [Proportions of "Light" and "Heavy" Oil of Cinnamon]. Haensel's Report. Oct., 1905, 11.

In a recent distillation of cinnamon chips, the heavy and light oils were collected separately. The light oil had the sp. gr. 0.990 and contained 47 per cent. of aldehydes. The heavy oil, sp. gr. 1.025, contained 67 per cent. of aldehydes. About 66.1 per cent. of the total oil obtained was "light" oil, and 33.3 per cent. "heavy" oil.—J. O. B.

Acetaldehyde; Action of Sodium Sulphite on —. Seyewitz and Bardin. Bull. Soc. Chim., 1905, 33, 1312.—1314.

FIFTY c.c. of a 15 per cent. solution of anhydrous sodium sulphite are slowly added to 200 grms. of 95 per cent. acetaldehyde, the temperature being kept at 0° C., and the mixture is extracted with ether. The extracts are evaporated, and the residue is distilled, the products consisting chiefly of crotonic aldehyde and crotonic acid. The above conditions are stated to give the best yield of crotonic aldehyde (about 40 per cent. of the theoretical yield).—T. F. B.

Mercuric Chloride; Solubility of — in Ethyl Acetate and Acetone. A. H. W. Aten. Z. physik. Chem., 1905, 54, 121—123.

THE results of the author's determinations are shown in the following table:—

Temperature.	Composition of Solution in Mols. per cent. of Mercuric Chloride	
	Ethyl acetate solution	Acetone solution.
—15	9.10	14.5
0	9.25	14.3
+10	—	18.7
+17	—	23.5
+25	9.15	22.2

In the column relating to the acetone solution, the first three numbers refer to the case of the solution containing a compound of mercuric chloride and acetone, $\text{HgCl}_2 \cdot (\text{CH}_3)_2\text{CO}$, as solid constituent, whilst the last three refer to mercuric chloride as the solid substance. On adding mercuric chloride to acetone at temperatures below 10° C.,

it dissolves rapidly and abundantly at first, but after a short time, a compound of the composition given above, separates from the clear solution. The solubility curve for mercuric chloride in acetone consists of two distinct branches, corresponding to mercuric chloride and the compound of the same with acetone respectively, and intersecting at the transition point which is 13° C. for a solution containing 27 mols. per cent. of mercuric chloride.—A. S.

Urotropine [Hexamethylenetetramine]; Examination of —. A. Wöhlk. XXIII., page. 93.

Cinchona Exports from Java. Chem. and Druggist, Jan. 5, 1906.

THE N.V. Nederlandsche Veem at Amsterdam reports the shipments from Java to Europe as follows:—

	Amst. lb.	Amst. lb.
1905 ..	15,399,000	1898 .. 11,150,000
1904 ..	14,450,000	1897 .. 8,437,000
1903 ..	13,725,000	1896 .. 10,079,000
1902 ..	13,345,000	1895 .. 8,827,700
1901 ..	12,799,000	1894 .. 8,917,700
1900 ..	10,780,000	1893 .. 7,342,000
1899 ..	11,409,800	

(Amst. pound = 1.1 English pound.)

With regard to the possibility of an export-tax on Java cinchona, which has been mooted at several quarters, it now appears from the report of the Java Budget, which has just been issued, that cinchona has not been selected for an export duty. [T.R.]

ENGLISH PATENTS.

Camphor; Manufacture of —. A. Zimmermann, London. From Chem. Fabr. auf Actien, vorm. E. Schering, Berlin. Eng. Pat. 9008, April 28, 1905.

A MIXTURE of borneol vapour and oxygen or air, at about 100° C., is passed over some catalytic agent, e.g., spirals of copper wire or platinum asbestos, or broken earthenware contained in a tube; after about eight hours, the product is stated to contain about 25 per cent. of camphor. (Compare Eng. Pat. 9559 of 1905; this J., 1905, 902.)—T. F. B.

Protocatechuic Aldehyde; Process for Manufacturing —. E. H., and K. Fritzsche (Schimmel und Co.), Mühlitz-Leipzig, Germany. Eng. Pat. 18,992, Sept. 20, 1905. Under Int. Conv., Oct. 17, 1904.

PIPERONAL or piperonal chloride is heated with a halogen compound of sulphur or of sulphuric acid; the dichloro-piperonal chloride thus produced (which is chlorinated in the methylene group only) is converted into proto-catechuic aldehyde by boiling with water. 15.4 kilos. of piperonal may be heated with 26.8 kilos. of sulphuryl chloride to about 80° C.; the product of the reaction is boiled with water, and the aldehyde extracted with ether.—T. F. B.

(Continued from page 39.)

Sensitive Preparations (and Photographic Papers) Darkening Directly in Light, and Containing no Soluble Silver Salts: Production of —. A. and L. Lumière. Phot. J., 1905, 45, 408.

ALT. "printing out" papers at present in use contain an excess of soluble silver salts, which cause deterioration of the emulsion, as well as favouring the formation of silver stains on the negative and print. It has been found that, when reducing agents are added to a silver halide emulsion (especially a chloride emulsion), containing no excess of soluble silver salts, the emulsion is darkened by light. Among organic substances, amine compounds are less active in this respect than hydroxy compounds, and with the latter the reducing properties depend on the number of hydroxy groups present: resorcinol is very suitable for use in making such papers. Of inorganic substances, manganous salts, nitrites and arsenites are of interest in this connection. The reducing agent is incorporated with the silver emulsion, which may be prepared with gelatin, casein, albumin, collodion, &c. Papers prepared as indicated above are stated to possess excellent keeping properties, and to have no tendency when damp to stain negatives. They are toned and fixed in the same manner as ordinary "printing out" papers.—T. F. B.

Reproduction: Process of Polychrome — by Chemical Selection of the Colours, the Original being Regenerated. T. M. J. Truchelut. Fr. Pat. 350,289, Nov. 3, 1904.

This specification relates to a process of reproducing

objects coloured only by the three fundamental colours, the red consisting of a mixture of an Eosin lake and nickel phosphate; the blue, a Methylene Blue lake and mercurous chloride, and the yellow, a Martius' Yellow lake and lead sulphate. The original is first treated with a 1 per cent. solution of potassium ferricyanide, washed, treated with a 10 per cent. oxalic acid solution and washed again: this is said to convert the red portions of the image into orange, and to decolorise the yellow. The resulting image is photographed, and printing plates made from this and the subsequent negatives. The image is now treated with an ammoniacal solution of potassium ferrocyanide, washed, treated with 2 per cent. sulphuric acid, and photographed. The image is further treated with a 5 per cent. ferric chloride solution, washed, and treated with an 8 per cent. potassium bichromate solution, washed, and immersed in 2 per cent. sulphuric acid and again photographed. The printing plates obtained from these negatives correspond to the red, blue and yellow portions respectively of the original. By now washing the treated image in water, it is stated to be restored to its original colours, the only difference being that the Martius' Yellow portions are replaced by lead chromate. The printing plates are inked with suitable colours and utilised for three-colour printing in the usual manner.

XXII.—EXPLOSIVES, MATCHES, Etc.

(Continued from page 40.)

Match Industry of Italy. Bd. of Trade J., Jan. 4, 1906.

THE manufacture of phosphorus matches in Italy dates back to 1831, the first match factory being established at Empoli. This factory is still in existence, employing about 50 workmen. The most important centres of the industry are in Piedmont and Tuscany.

In 1880 the exports of wax matches amounted to 9357 quintals valued at 2,198,825 lire, and 6079 quintals of wooden matches valued at 243,160 lire. The industry showed a notable development between the years 1881 and 1890: it received, however, a set-back in 1895 when a law was passed imposing a tax on the manufacture of matches. Before the promulgation of this law there were 489 manufactories of wooden matches and 40 manufactories of wax matches, but this number has since shown a great decrease, and at the present day there are only 220 factories of both kinds. The formation of a company combining over a dozen large firms has brought about the closure of a large number of small factories. In 1903—04 the total output of the combine amounted to 8987 million wooden matches and 25,084 million wax matches, the total output of the country being 43,178 million wooden matches and 20,523 million wax matches.

The importation of wooden matches into Italy is very small, but there is a fairly large import of wax matches.

White and red phosphorus used in the manufacture of wax matches comes from Germany, France, and Great Britain. During the years 1902 and 1903 the average import of phosphorus for match making amounted to about 790 quintals. The 216 factories employed, during 1903—04, 6699 persons. The industry is mainly carried on by hand, very few factories possessing machinery. Amongst the latter, two factories have gas power, one hydraulic, ten steam, and one electric. [T.R.]

ENGLISH PATENT.

Match Compositions. W. Bokmayor, Mödling, and A. Swoboda, Vienna. Eng. Pat. 20,350, Oct. 9, 1905.

See Fr. Pat. 355,846 of 1905; this J., 1905, 1256.—T. F. B.

UNITED STATES PATENT.

Smokeless Powder; Apparatus for Making — G. W. Gentien and R. S. Waddell, Peoria, Ill. U.S. Pat. 808,036, Dec. 19, 1905.

THE claims include the combination of a receptacle or tank, traversed by a hollow revolving shaft carrying a number of hollow arms communicating with the interior of the shaft; a stationary pipe, for compressed air, fitting in the hollow shaft, and provided on the lower side with ports that coincide with the hollow arms; a liquid-supply pipe, extending into and discharging within the air-pipe; a valve controlling the liquid-supply pipe; nozzles discharging into the tank, near the bottom; a pipe supplying compressed air to the hollow arms and nozzles, and surrounded with a steam jacket; and means for introducing material into and discharging the same from the receptacle.—C. R.

FRENCH PATENT.

Explosive (Non-Hygroscopic). Soc. Anon. de la Poudrière de Ben-Ahin. Fr. Pat. 357,233, Aug. 25, 1905.

CLAIM is made for a process of coating dry, finely powdered sodium nitrate with a natural or a nitrated hydrocarbon of the fatty acid series, by melting the hydrocarbon or its nitrated derivative, if solid or semi-solid, and mixing it with the salt, or if already liquid, by simply mixing the two in the cold. The combustible base thus obtained is non-hygroscopic, and may be mixed with other ingredients to form explosive powders for mines, &c. Suitable mixtures claimed are as follows:—(a) sodium nitrate, 55 to 70; solid hydrocarbon, 10 to 20; sulphur, 6 to 12; and carbon, 10 to 16 per cent. (b) sodium nitrate, 20 to 40; highly nitrated hydrocarbon 20 to 30 per cent.; and potassium chlorate, 40 to 60 per cent. (c) sodium nitrate, 35; liquid hydrocarbon, 28; and ammonium perchlorate, 37 per cent. Explosives prepared on these lines are stated to resist moisture, to be free from danger, and to be equal to the best nitro-glycerin products.

—C. A. M.

XXIII.—ANALYTICAL CHEMISTRY.

(Continued from page 43.)

APPARATUS, ETC.

Gases; Portable Apparatus for the Analysis of Flue — C. J. Wilson. Proc. Inst. Civil Eng., 1905, 162, Paper No. 3580.

THE portable apparatus shown in the figure (scale $1\frac{1}{2}$ in. = 1 ft.) is proposed for the analysis of flue gases. It consists of a water-jacketed eudiometer L connected with an absorption bulb C; between those is a three-way cock A, so that C and L can be connected together, or either of them with the exit tube P in the stopcock. D and E contain mercury, and are adjustable vertically. The apparatus is first completely filled with mercury, when P is connected with the eudiometer, and the gas is passed into it, and brought to the desired volume. Stopcock A is then turned so as to connect P with C; this latter is now filled with the necessary absorbing solution by placing a small beaker containing the latter under P and lowering D. Tap B is then closed, E is raised, and L is

connected with C, thus sending the gas into C. When absorption is complete, E is lowered until the gas has flowed back into L, when tap A is turned, so that the absorbing solution passes out at P and is collected. The bulb C is then washed out with water, and a second absorbing solution run in, the absorption being repeated as before.—T. F. B.

ENGLISH PATENTS.

Loss or Gain in Weight; Apparatus for use in Ascertaining the Extent to which Materials Lose or Gain in Weight in being subjected to Drying or Exposure to Moisture or other Treatment tending to Cause — and for use in Weighing of other kinds. T. Oxley, Manchester. Eng. Pat. 20,653, Oct. 12, 1905.

THE improvement consists in supporting the beam and the scale-pan by arms projecting from the beam, so as to allow a rider, which slides along the beam, to be set in any position from one in the vertical plane of the beam support, to one in the vertical plane of the scale-pan support. By making the rider a definite fraction of the fixed weight, and by placing it in the vertical plane of the latter and balancing the two by the material to be examined, it is possible, when any alteration in the weight of the material has taken place, and the balance is again restored by moving the rider, to read off the loss or gain in weight as a percentage or fraction of the whole weight. This can be done at once from the marking of the scale and without calculation.—W. H. C.

Photometers or Apparatus for Testing the Intensity of Light, comprising the use of a Selenium Cell. T. Torda and V. Bornand, Birmingham. Eng. Pat. 4020, Feb. 27, 1905.

CLAIM is made for improvements in photometers comprising a device in combination with the use of a selenium cell and current meter, whereby the selenium cell is exposed to the light rays for a certain period, "which, together with the time of rest in darkness, is automatically effected in the required proportions."—T. H. P.

INORGANIC—QUANTITATIVE.

Acetylene; Reaction of —, on Iodic Anhydride. G. F. Jaubert. Comptes rend., 1905, 141, 1232—1234.

When air containing acetylene is passed over iodic

pounds are described and claimed:—Metho-ethenylthano oxide,

metho-ethenylisopentano oxide, and methaphenylethylenyl oxide. When treated with amines, these oxides yield amino-alcohols, stated to be of therapeutic value; when reduced, they produce alcohols. They can also be converted, e.g., by mineral acids, into odorous aldehydes.

—T. F. B.

Dialkylmalonalurens: Process for Making Derivatives of Dialkylmalonic Acid and —. Farbwerke vorm. Meister, Lucius and Brüning. Fr. Pat. 350,255, Oct. 24, 1904.

When dimethyl- or methylethylmalonic esters are condensed with dicyanodiamide by means of a solution of sodium in methyl or ethyl alcohol, or when diethylmalonic esters are similarly condensed by aid of a solution of sodium in methyl alcohol, intermediate products are obtained which, when heated with acids, are converted into the corresponding dialkylmalonalurens. XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(Continued from page 39.)

Sensitive Preparations (and Photographic Papers) Darkening Directly in Light, and Containing no Soluble Silver Salts: Production of —. A. and L. Lumière. Phot. J., 1905, 45, 408.

ALT. "printing out" papers at present in use contain an excess of soluble silver salts, which cause deterioration of the emulsion, as well as favouring the formation of silver stains on the negative and print. It has been found that, when reducing agents are added to a silver halide emulsion (especially a chloride emulsion), containing no excess of soluble silver salts, the emulsion is darkened by light. Among organic substances, amine compounds are less active in this respect than hydroxy compounds, and with the latter the reducing properties depend on the number of hydroxy groups present: resorcinol is very suitable for use in making such papers. Of inorganic substances, manganous salts, nitrites and arsenites are of interest in this connection. The reducing agent is incorporated with the silver emulsion, which may be prepared with gelatin, casein, albumin, collodion, &c. Papers prepared as indicated above are stated to possess excellent keeping properties, and to have no tendency when damp to stain negatives. They are toned and fixed in the same manner as ordinary "printing out" papers.—T. F. B.

FRENCH PATENTS.

Reproduction: Process of Polychrome — by Chemical Selection of the Colours, the Original being Regenerated. T. M. J. Truchelut. Fr. Pat. 350,289, Nov. 3, 1904.

This specification relates to a process of reproducing

objects coloured only by the three fundamental colours, the red consisting of a mixture of an Eosin lake and nickel phosphate; the blue, a Methylene Blue lake and mercurous chloride, and the yellow, a Martius' Yellow lake and lead sulphate. The original is first treated with a 1 per cent. solution of potassium ferricyanide, washed, treated with a 10 per cent. oxalic acid solution and washed again: this is said to convert the red portions of the image into orange, and to decolorise the yellow. The resulting image is photographed, and printing plates made from this and the subsequent negatives. The image is now treated with an ammoniacal solution of potassium ferrocyanide, washed, treated with 2 per cent. sulphuric acid, and photographed. The image is further treated with a 5 per cent. ferric chloride solution, washed, and treated with an 8 per cent. potassium bichromate solution, washed, and immersed in 2 per cent. sulphuric acid and again photographed. The printing plates obtained from these negatives correspond to the red, blue and yellow portions respectively of the original. By now washing the treated image in water, it is stated to be restored to its original colours, the only difference being that the Martius' Yellow portions are replaced by lead chromate. The printing plates are inked with suitable colours and utilised for three-colour printing in the usual manner.

Flashlight Powders. Farbenfabr. vorm. F. Bayer and Co. Fr. Pat. 350,308, Nov. 15, 1904.

SEE Eng. Pat. 24,087 of 1904; this J., 1905, 1031.—T. F. B.

Photographic Papers for Producing Images Sensitive to Daylight: Phosphorescent —. R. Ban. Fr. Pat. 356,735, Aug. 7, 1905.

One cubic decimetre of the paper pulp is mixed with 150 grms. of calcium sulphide, 30 grms. of zinc sulphide and 20 grms. of strontium sulphide. The paste is made into paper in the usual manner, and this, when dry, is rendered impervious with a lac varnish. The paper is now coated with a sensitive silver emulsion. It gives phosphorescent prints when exposed beneath a negative and finished as usual.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

(Continued from page 40.)

Match Industry of Italy. Bd. of Trade J., Jan. 4, 1906.

THE manufacture of phosphorus matches in Italy dates back to 1831, the first match factory being established at Empoli. This factory is still in existence, employing about 50 workmen. The most important centres of the industry are in Piedmont and Tuscany.

In 1880 the exports of wax matches amounted to 9357 quintals valued at 2,198,825 lire, and 6079 quintals of wooden matches valued at 243,160 lire. The industry showed a notable development between the years 1881 and 1890: it received, however, a set-back in 1895 when a law was passed imposing a tax on the manufacture of matches. Before the promulgation of this law there were 489 manufactories of wooden matches and 40 manufactories of wax matches, but this number has since shown a great decrease, and at the present day there are only 220 factories of both kinds. The formation of a company combining over a dozen large firms has brought about the closure of a large number of small factories. In 1903—04 the total output of the combine amounted to 8987 million wooden matches and 25,084 million wax matches, the total output of the country being 43,178 million wooden matches and 20,523 million wax matches.

The importation of wooden matches into Italy is very small, but there is a fairly large import of wax matches.

citrate and removed, while the barium malate remains in solution. The liquid is evaporated on the water-bath and when cool, treated with four times its volume of alcohol. The precipitate is collected with the aid of the filter pump, washed with alcohol and transferred to a platinum capsule. Ten c.c. of 10 per cent. sodium hydroxide solution are added, and the whole evaporated to dryness on the water-bath. The residue is then heated for about two hours at 120° – 130° C. The product is dissolved in dilute hydrochloric acid, decolorised with animal charcoal, filtered, and shaken out with ether, leaving the ether in contact with the aqueous liquid for half an hour, if the amount of acid be but small. On separating and evaporating the ethereal layer, fumaric acid, derived from malic acid, is left.

By this test, the author finds that malic acid is not present as a natural constituent in raspberry juice, which is, however, rich in citric acid, and contains very little tartaric acid.—J. O. B.

Urotropine (Hexamethylenetetramine): Examination of —. A. Wihlk. Z. anal. Chem., 1905, 44, 765–766.

The author has found that Nessler's solution (an alkaline solution of mercuric and potassium iodide) forms a very satisfactory reagent for testing the purity of hexamethylenetetramine, since it is capable of indicating the presence of ammonium salts, amines and paraformaldehyde, which are the most common impurities of this compound. Pure hexamethylenetetramine, when dissolved in water and boiled with Nessler's solution, will not give either a yellowish-brown or brown colour (ammonia or amines) or a precipitate of mercury (formaldehyde).—A. S.

Euphorbium Resin [and Reaction for same]. A. Tschirch and Paul. XIII B., page 82.

ORGANIC—QUANTITATIVE.

Trehalose: Detection and Determination of — in Plants by means of the Enzyme Trehalase. P. Harang. J. Pharm. Chem., 1906, 23, 16–20.

The presence of trehalose in mushrooms and fungi may be detected, and its proportion determined by converting it into dextrose by the action of the enzyme trehalase. An active preparation of this enzyme is obtained by cultivating *Aspergillus niger* in Raulin's solution. After about 30 hours at 33° C. the nutrient liquid is decanted off and replaced by water, the operation being performed five or six times. The mould is then grown, the culture is separated, pressed and treated with 95 per cent. alcohol for three hours, drained, and then dried and powdered. This powder will invert twice its weight of trehalose in 48 hours at 33° C. To extract the trehalose, the freshly-cut plants are chopped up and extracted twice in succession with an equal weight of boiling 80 per cent. alcohol, the extracts being mixed, filtered and concentrated *in vacuo* to a small volume. The liquid is mixed with four times its volume of 80 per cent. alcohol and the precipitate allowed to settle. The solution is poured off and the precipitate again treated with water and alcohol in a similar manner. The alcoholic liquids, containing the trehalose are evaporated to dryness *in vacuo*; the sugar is dissolved in thymolised water and treated with the *Aspergillus* preparation at 33° C. After 10 days the inversion is complete, and the quantity of trehalose, $[\alpha]_D^{20}$ = 197.3°, is calculated from the decrease in optical rotation. In *Clitocybe nebularia*, the author found 0.94 per cent. of trehalose calculated on the fresh plant substance.—J. F. B.

Tannin in Wine: Determination of —. L. Kramszky. Z. anal. Chem., 1905, 44, 756–766.

For the determination of tannin in wines, the author uses as a precipitant an ammoniacal solution of zinc sulphate. The normal constituents of wine, including the colouring matter, have no influence on the precipitation of tannin by this reagent. The zinc solution is prepared by dissolving about 25 grms. of pure zinc sulphate in water, adding ammonia until the precipitate formed at first, just re-dissolves, then adding a further 300 c.c. of ammonia and making up to 1 litre. Fifty c.c. of a red wine or

100 c.c. of a white wine are made alkaline with ammonia and treated with 20 c.c. of the zinc solution, the mixture is stirred, and made up to 300 c.c. with warm water. After standing, the precipitate is washed several times by decantation with hot, faintly ammoniacal water, and collected in a Gooch crucible containing a little asbestos. The precipitate is dried at 100° – 130° C., weighed, ignited in a tared crucible, with the addition, finally, of a few drops of nitric acid, and again weighed. The difference between the weights of the dried and ignited precipitates gives the quantity of tannin.—A. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

(Continued from page 44.)

Phosphorus Tribromide and Tri-iodide: Action of Ammonia on —. [Production of Phosphimide and Phosphinide.] C. Hugot. Comptes rend., 1905, 141, 1235–1237.

AMMONIA reacts at 65° C. on phosphorus tribromide, at slightly higher temperatures on the tri-iodide, forming yellow phosphimide

This can be separated from the ammoniacal ammonium bromide formed, but dissolves in the corresponding iodine compound. Whether isolated or in solution, it slowly decomposes (more rapidly at higher temperatures) yielding phosphinide, $-2\text{P}(\text{NH}_2)_3 \rightarrow \text{P}_2(\text{NH})_3 + 3\text{NH}_3$. Phosphinide is a brown substance which decomposes on heating.—J. T. D.

Selenious Acid: Action of Dextrose on —. [Amorphous Selenium.] O. de Coninck and Chauvenet. Comptes rend., 1905, 141, 1234–1235.

When solutions of dextrose and selenious (or selenic) acid are gently heated together, the selenium separated is in a semi-colloidal condition red, amorphous, insoluble in carbon bisulphide, extremely finely divided and difficult to separate from the liquid by settlement or filtration. At 100° C. it is partially transformed into ordinary black selenium. J. T. D.

Digitoxose. H. Kiliani. Ber., 1905, 38, 4040–4043.

DIGITOXOSE, $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ (see this J., 1898, 1174) is now shown to be an aldose sugar having the constitution $\text{CH}_2(\text{CHOH})_3\text{CH}_2\text{COH}$. It does not yield an osazone, and it is readily oxidised in aqueous solution by bromine to digitoxonic acid, which exists in the form of a lactone and yields an uncrystallisable calcium salt. Digitoxose is energetically oxidised by concentrated nitric acid, but if the calcium salt of digitoxonic acid be treated with nitric acid, a dihydroxylglutaric acid is the main product, thus confirming the above constitutional formula for the sugar. —J. F. B.

Prizes.

Portland Cement: Research on —.

THE Prussian Government and the German Society of Portland Cement Manufacturers offer premiums to the amount collectively of 3000 marks (about £150) for essays on the processes which take place in the hardening of hydraulic cements. The essays which take as general subject matter the demonstration of the properties and of the induration process of calcareous hydraulic cements, synthetically, analytically, microscopically and mineralogically as applied to hardening in air, fresh and sea water, may deal with all or any of the following questions:—(a) To prove whether silicic acid, alumina and oxide of iron combine with lime as crystalloids in stable proportions, or as colloids in varying proportions. (b) To prove whether double combinations result between silicic acid, alumina, and oxide of iron with lime, and in what manner these substances take part in the hardening process. (c) Consideration of the swelling phenomenon which accompanies the hydraulic hardening. (d) Consideration of the influence of the temperature and the duration of the burning process on the different kinds of hydraulic cements. (e) Properties of puzzolana and its hardening with lime; beginning with silicic acid, as the most active and prominent puzzolana, alumina, oxide of iron, and manganese,

independently and in combination with silicic acid, either as natural or artificial puzzuolana. The papers must be written in German and be submitted under a *nom de plume* to the Ministry of Public Works, 80, Wilhelmstrasse, Berlin, on or before Dec. 31, 1906.

Trade Report.

UNITED KINGDOM; TRADE OF — IN 1905.

Bd. of Trade J., Jan. 11, 1906.

The following table shows the value of certain imports from foreign countries and British possessions during the twelve months ended December 31st last, as compared with the corresponding periods of the two previous years:—

	Year ended 31st December.		
	1903.	1904.	1905.
RAW MATERIALS AND ARTICLES MAINLY UNMANUFACTURED—	£	£	£
Coal, coke and patent fuel	3,987	2,689	42,582
Iron ore, scrap iron and steel	4,887,793	4,599,200	5,530,784
Other metallic ores	5,915,491	6,597,702	7,611,185
Wood and timber	27,122,956	23,637,985	23,276,358
Cotton	45,026,578	55,924,825	52,370,878

SAMPLES OF BRITISH GOODS; EXHIBITION OF — AT CAPE TOWN AND CHICAGO.

Bd. of Trade J., Jan. 4, 1906.

The Board of Trade desire to draw attention to the fact that Mr. E. J. Cattell (the Secretary of the Cape Town Chamber of Commerce), and Mr. A. Finn, H.M. Consul at Chicago, are prepared to receive samples from British manufacturers, at the manufacturers' risk, and to exhibit such samples, respectively, at the Chamber of Commerce and at the Consulate. Prices should be attached in sterling l.s. or c.i.f., or if possible in currency, landed, duty paid. No charge is proposed at Cape Town, but at Chicago a fee of 5s. per square foot occupied by the exhibitors has to be made for any period not longer than a year. Messrs. Hickie, Borman, Grant and Co., of 14, Waterloo Place, London, S.W., have consented to act as forwarding agents for any packages intended for the sample room at Chicago.

DRUG AND CHEMICAL TRADE IN 1905.

J. C. Umney. *Chamber of Com. J., Jan., 1906.*

The shrinkage in value of drugs and chemicals reached an acute stage at the end of 1904. In the aggregate the volume of business in 1905 has shown improvement, but it has been apparently in export rather than in home trade, and it may be that the ratio of profits has not been maintained, and it is on this account that the increased exports as shown in the Board of Trade returns, may be an indication rather of weak trade at home, and a desire to keep factories running and men employed by a forcing of export trade. Heavy chemicals have shown an upward tendency during the past year. Potash salts, principally due to the shortage of the beet crop in the previous autumn, have been on a higher scale. Tartaric acid has about maintained its level, but higher rates have ruled for citric acid, and although at the close of the year, prices are hardly at their best, yet they finish at least 25 per cent. higher than the corresponding time of 1904. Metals generally have shown a strong upward tendency. The appreciation in the value of antimony at the close of 1904 has been practically maintained. Tin has advanced to almost prohibitive prices, whilst zinc, and latterly copper, have also shown considerable advances. Bismuth, which at the close of 1904, was advanced by about 20 per cent., has, after a small advance at the beginning of the year, suffered a large drop at the hands of the syndicate controlling its sale during the last few weeks. Mercury has varied a trifle in price, but competition in materials has presumably reduced the level of profit to practically nothing, so that the sooner a reasonable agreement of prices is made the better, at any rate, for the manufacturers. Silver also shows considerable appreciation in value, and this has naturally had a corresponding effect in those products coming to this country from China, &c. The very considerable advance that was made in iodine during the month of February resulted apparently in attracting considerable competition to this country both from Japan and also Germany. Chloroform, which as a result of the breaking of the bleaching powder Convention, dropped to the lowest point on record during 1904, has been raised, by agreement of manufacturers, by at least 33 per cent., and there is every indication that prices will be maintained. French lavender flowers and their products have shown considerable increase in price, partly due to the drought, which has also affected prices of saffron, which are very high, and it is stated has practically ruined the Spanish olive oil crop, although fortunately, the Italian is unaffected. In camphor, prices have reached a very high level, and are higher and firmer than they have been during the past 12 months. Whether the development of the Japanese celluloid industry has resulted in a considerably increased home demand or not, is not clear. American turpentine has shown violent fluctuations, closing firm, but the prices that have ruled during the year appear to indicate fairly plainly that most of the so-called turpentine substitutes have not been efficient ones. Norwegian cod liver oil, which had shown firmness during the early autumn, closed flat, but prices can hardly be lower in view of the comparatively small stocks held, and in the event of the cod fishing being either delayed, or the yield of oil poor, prices should show considerable advances. In alkaloïds there has been but little speculation. Quinine appears to have ceased to attract, whilst the decreased consumption of cocaine, owing to the restrictions placed upon it in India and elsewhere, has had the general effect of depressing prices, with a slight spurt only just at the end of the year.

New Books.

ADOLF VON BAEYER'S GESAMMELTE WERKE. Herausgegeben zur Feier des siebenzigsten Geburtstages des Autors, von seinen Schülern und Freunden. In Zwei Bänden. Mit dem Porträt des Verfassers in Photogravure, &c. Friedrich Vieweg und Sohn, in Braunschweig, 1905. Price M.16. Bound in cloth, M.20.

Two large 8vo volumes; Vol. I. containing Baeayer's portrait as frontispiece; preface by the Committee; a chapter by Baeayer entitled "Erinnerungen aus meinem Leben, 1835-1905," including "Erinnerungen aus der Strassburger Studienzeit, 1872-1876," by Emil Fischer. Then a chapter entitled "Meine wissenschaftliche Arbeiten in den Jahren 1865-1905," and finally one entitled "Zur Geschichte der Indigo-Synthese." Following these is a compendium, filling 63 pages, of the titles of Researches emanating from Baeayer's Laboratories in Berlin, Strassburg and Munich, with the names of those who co-operated with him. Vol. I. contains 990 pages and Vol. II. 1169, with a final alphabetical index of subjects. These researches are classified in a special Table of Contents (CXIX. to CXXXII.), according to order of date, whilst in the text itself they are collected into Monographs, according to the General Themes or Subjects treated of. Thus, nineteen groups are dealt with, and are as follows:—I. Organic Arsenic Compounds. II. The Uric Acid Group. III. Indigo. IV. Investigations which have relationship to the Indigo researches. V. Pyrrol and the Pyridino Bases. VI. Dehydration and Condensation. VII. Phthaleins. VIII. The Chemistry of the Hydro-aromatic Compounds, Building up of Mellic Acid, and Constitution of Benzene. IX. Investigations on the Terpenes. X. The Nitroso Compounds. XI. Furfural. XII. On the Acetylene Compounds and the Theory of Tension. XIII. The Peroxides. XIV. The Basic Properties of Oxygen. XV. Dibenzalacetone and Triphenylmethane. XVI. Treatises on Certain Substances in the Aromatic Series. XVII. Similar Treatises on Certain Bodies of the Aliphatic Group. XVIII. Nomenclature. XIX. Miscellaneous.

KURZES LEHRBUCH DER ORGANISCHEN CHEMIE. VON Prof. Dr. A. BEINTISEN. 9te Auflage, Bearbeitet in Gemeinschaft mit Dr. Ernst Mohr. Friedrich Vieweg und Sohn, Braunschweig, 1906. Price M.11. Bound in cloth, M.11.80.

8vo volume, containing 601 pages of subject matter, and an alphabetical index. After an introduction of 34 pages dealing with general methods and theories, the main subject is treated of under the following divisions:—Group I. Methane Derivatives. II. Chemistry of the Isocyclic Compounds. III. The Heterocyclic Compounds, including those of which each contains in the molecular ring or cycle, three, four, five or six atomic members or groups.

DIE ELEKTROLYSE GESCHMOLZENER SALZE. Monographie n über angewandte Elektrochemie. Zweiter Theil: Das Gesetz von Faraday; die Ueberführung und Wanderung der Ionen; das Leitvermögen. Von RICHARD LORENZ, Ph.D., Professor für Elektrochemie und Physikalische Chemie am eidgen. Polytechnikum in Zürich. Wilhelm Knapp's Verlag. Halle a. S., 1905. Price M.8.

8vo volume, containing 243 pages of subject matter, with 59 illustrations, and including from two to three pages of a bibliographic index. There are alphabetical indexes of the names of authors and of subjects. The subject is divided as follows:—A. Faraday's Law; B. The Movements of the Ions; and C. Conductivity. APPENDIX I. Conductivity of Glass, Porcelain and Quartz. APPENDIX II. Various Statements in Literature as to the Conductivity of Oxides, Sulphides and Selenides.

independently and in combination with silicic acid, either as natural or artificial puzzuolana. The papers must be written in German and be submitted under a *nom de plume* to the Ministry of Public Works, 80, Wilhelmstrasse, Berlin, on or before Dec. 31, 1906.

Trade Report.

UNITED KINGDOM; TRADE OF — IN 1905.

Bd. of Trade J., Jan. 11, 1906.

The following table shows the value of certain imports from foreign countries and British possessions during the twelve months ended December 31st last, as compared with the corresponding periods of the two previous years:—

	Year ended 31st December.		
	1903.	1904.	1905.
RAW MATERIALS AND ARTICLES MAINLY UNMANUFACTURED—			
Coal, coke and patent fuel	3,987	2,689	42,582
Iron ore, scrap iron and steel	4,887,793	4,599,200	5,530,784
Other metallic ores	5,915,491	6,597,702	7,611,185
Wood and timber	27,122,956	23,637,985	23,276,358
Cotton	45,026,578	55,924,825	52,370,878
Wool	23,809,809	23,316,455	26,648,261
Other textile materials	11,826,896	18,039,669	14,517,288
Oil-seeds, nuts, oils, fats and gums	24,461,171	25,290,505	23,594,019
Hides and undressed skins	7,381,872	6,576,310	8,084,824
Materials for paper making	3,431,467	3,554,133	3,804,692
ARTICLES WHOLLY OR MAINLY MANUFACTURED—			
Iron and steel and manufactures thereof	8,662,481	8,216,772	8,568,571
Other metals and manufactures thereof	18,511,270	20,053,877	21,840,599
Chemicals, drugs, dyes and colours	8,848,292	9,211,770	9,624,607
Leather and manufactures thereof	11,313,951	10,893,182	11,037,762
Earthenware and glass	4,780,739	4,337,273	4,319,910
Paper	4,850,183	4,940,619	5,156,145

The value of the exports of home produce, also of foreign and colonial produce, during the 12 months of 1905, as compared with 1904 and 1903, is shown in the following table:—

	Year ended 31st December		
	1903.	1904.	1905.
RAW MATERIALS AND ARTICLES MAINLY UNMANUFACTURED—			
Coal, coke and patent fuel	27,262,786	26,862,386	20,661,117
Iron ore, scrap iron, and steel	453,946	500,621	474,866
Other metallic ores	134,843	130,630	116,011
Wood and timber	51,104	67,593	79,046
Cotton	1,092,997	1,613,737	1,744,772
Other textile materials	128,385	170,672	156,578
Oil-seeds, nuts, oils, fats and gums	2,978,551	2,759,019	2,597,319
Hides and undressed skins	1,276,836	1,428,041	1,854,526
Materials for paper making	409,624	428,481	518,623
ARTICLES WHOLLY AND MAINLY MANUFACTURED—			
Iron and steel and manufactures thereof	30,399,261	28,006,671	31,827,142
Other metals and manufactures thereof	6,968,305	6,991,421	8,934,590
Chemicals, drugs, dyes and colours	13,544,551	13,647,449	14,525,195
Leather and manufactures thereof	4,946,609	4,758,999	5,638,574
Earthenware and glass	8,278,482	8,110,223	8,300,281
Paper	1,795,550	1,876,797	1,938,379

Subjoined are particulars in respect to imports and exports of articles of interest to chemical industry:—

Imports.

Articles.	Quantities.	Value in £.
Chemicals—		
Bleaching materials	236,398 cwt.	61,802
Borax	254,608 ..	103,565
Brimstone	400,313 ..	99,783
Coal products (not dyes)	93,303 ..	66,477
Cream of tartar	*66,840 ..	247,881
Glycerin	*79,924 ..	141,630
Muriate of ammonia	4,599 ..	6,393
Potassium nitrate	1182,052 ..	173,689
Soda compounds	*365,704 ..	115,606
Sulphuric acid	*92,691 ..	7,224
Tartaric acid	36,443 ..	177,196
Unenumerated	—	*1,043,008
Condensed milk	33,944 ..	62,642
.. (sweetened)	769,888 ..	1,522,261
Drugs and medicines—		
Cinchona	*31,251 ..	74,724
Quinine	1708,866 oz.	32,708
Gum arabic	73,312 cwt.	*105,697
Lac-dye, shellac, &c.	199,772 ..	755,730
Mineral water	*1,409,922 doz. bots.	308,515
Oils (coco, cotton, olive and palm)	—	600,449
Petroleum	300,110,335 gals.	5,423,115
Quicksilver	*2,552,586 lb.	125,768
Rosin	1,610,629 cwt.	67,842
Snecharin	*850,856 oz.	38,368
Scientific apparatus	—	846,920
Soap	*473,986 cwt.	500,430
Sugar (refined and unrefined)	*27,706,467 cwt.	19,484,785
Turpentine	526,699 ..	1,104,000
Yeast	*175,356 ..	365,860

* Notable increases.

† Notable decreases.

Exports.

Articles.	Quantities.	Value in £.
Aurated waters	*1,103,301 doz. bots.	180,751
Chemicals, drugs, &c.—		
Bleaching materials	*937,267 cwt.	192,043
Coal products (not dyes)	10,324,780 ..	1,347,674
Copper sulphate	155,893 tons	1,125,827
Cream of tartar	11,194 cwt.	4,612
Dye-stuffs	246,099 ..	378,314
Glycerin	147,169 ..	991,141
Manure (chemical)	661,204 tons	3,468,768
Muriate of ammonia	90,269 cwt.	128,292
Soda compounds	4,721,235 ..	1,436,524
Sulphuric acid	86,752 ..	34,706
Tartaric acid	1,572 ..	7,687
Unenumerated	—	2,484,719
Medicines—		
Quinine	891,578 oz.	48,657
Oils (coco, olive and palm)	—	70,638
Scientific instruments	—	599,460
Soap	1,230,310 cwt.	1,284,158
Vinegar	434,071 gals.	44,431

* Notable increases.

† Notable decreases.

SAMPLES OF BRITISH GOODS; EXHIBITION OF — AT CAPE TOWN AND CHICAGO.

Bd. of Trade J., Jan. 4, 1906.

The Board of Trade desire to draw attention to the fact that Mr. E. J. Cattell (the Secretary of the Cape Town Chamber of Commerce), and Mr. A. Finn, H.M. Consul at Chicago, are prepared to receive samples from British manufacturers, at the manufacturers' risk, and to exhibit such samples, respectively, at the Chamber of Commerce and at the Consulate. Prices should be attached in sterling l.s. or c.i.f., or if possible in currency, landed, duty paid. No charge is proposed at Cape Town, but at Chicago a fee of 5s. per square foot occupied by the exhibitors has to be made for any period not longer than a year. Messrs. Hickie, Borman, Grant and Co., of 14, Waterloo Place, London, S.W., have consented to act as forwarding agents for any packages intended for the sample room at Chicago.

February 15, 1968

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."
 Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised are accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

- [A.] 1158. Schmidt. *See under XVIII.*
 " 1204. Lake (Nordyke and Marmon Co.). *See under VII.*
 " 1245. Kobusch. Heating drums. Jan. 17.

Official Notices.

SOCIETY OF CHEMICAL INDUSTRY.

NOTICE OF EXTRAORDINARY GENERAL MEETING OF THE SOCIETY.

(Summoned pursuant to Bye Law 40.)

Notice is hereby given that an Extraordinary General Meeting of the Society will be held at 3.30 o'clock, precisely, in the afternoon of Tuesday, the twenty-seventh day of March, 1906, at the House of the Society of Arts, John Street, Adelphi, W.C., by kind permission of the Council of that Society, with the object of considering and adopting the resolution mentioned in the Requisition hereinafter set forth:—

"TO THE PRESIDENT AND COUNCIL OF THE SOCIETY OF CHEMICAL INDUSTRY."

We, the undersigned Members of the Society of Chemical Industry, hereby request that, in accordance with Bye-Law 40, you will convene an Extraordinary General Meeting of the Society with the object of considering, and if approved by the said Extraordinary Meeting, of adopting the following resolution (that is to say):—

RESOLUTION.
"That it is desirable that the Society of Chemical Industry as now existing should be incorporated under and subject to the grant of a Royal Charter and that the Council be and hereby is authorised to take all necessary steps to procure the grant of a Royal Charter of Incorporation."

Dated this twenty-second day of December, 1905.

Here follow signatures of the following:—

George Beilby.	Henry de Moseenthal.
V. G. Bloede.	Prof. Chas. E. Munroe.
Jas. H. Bowman.	Jas. P. Murray.
Eugene A. Byrnes.	Robert W. Neff.
Eustace Carey.	A. L. Norton.
Prof. Frank Clowes.	D. H. T. Peploe.
Frederick P. Dewey.	Dr. W. H. Perkin.
Dr. Edward Divers.	Dr. Frederick B. Power.
Dr. A. R. L. Dohme.	Sir William Ramsay.
Thos. Fairley.	Sir Boverton Rodwood.
Dr. Fred. W. Frenichs.	Walter F. Reid.
Oscar Guttman.	President Ira Remsen.
Samuel Hall.	Sir Henry E. Roseoe.
Jas. Otis Handy.	George D. Rosegarten.
Dr. R. J. Harrington.	Dr. Samuel P. Sadtler.
Dr. Edward Hart.	Alfred Gordon Salamon.
Otto Hohner.	Dr. Karl F. Stahl.
E. Grant Hooper.	H. E. Stuart.
David Howard.	Sir Joseph W. Swan.
H. Atg. Hunicke.	H. P. Talbot.
C. C. Hutchinson.	M. J. Taylor.
Prof. Edward H. Keiser.	E. C. Thompson.
Prof. W. R. Lang.	Dr. T. E. Thorpe.
Ivan Lovinstein.	Prof. W. A. Tilden.
Arthur R. Ling.	Thos. Tyrer.
Anthony McGill.	John H. Usmar.
Edward Mallinckrodt.	W. H. Van Winckel.
N. H. Martin.	S. S. Voorhoe.
Prof. R. Mekola.	Dr. W. H. Walker.
Dr. Rudolph Messel.	R. A. Wallace.
Dr. W. Lash Miller.	Charles Wightman.
Dr. Ludwig Mond.	Dr. H. W. Wiley.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome, commencing on April 25th, 1906. All communications should be addressed to the General Secretary, Prof. Vittorio Villavecchia, Via Panisperna, 89, Rome.

The attention of Members is drawn to the Notice which accompanies this issue of the Journal.

Deaths.

Meeting held at Burlington House, on Monday, January 8th, 1906.

MR. A. GORDON SALAMON IN THE CHAIR.

CINCHONA BARKS AND THEIR CULTIVATION.

BY DAVID HOWARD.*

I propose this evening to give a brief sketch of some of the results of the cultivation of Cinchona bark, and before doing so, will only venture on a mere reference to the previous history of the Cinchona barks and to the chemistry of their alkaloids; for the former I would refer anyone interested in the subject to the admirable work by Sir Clements Markham, entitled "Peruvian Bark," and for the latter to Leger's admirable monograph, "Les alcaloides des Quinquinas."

Quinine and its cognate alkaloids have hitherto only been found in the barks of the genus Cinchona and the allied genus Reingia. These are only found in a limited zone of the eastern slopes of the Andes, and nothing was known to Europeans of their medicinal properties till some time after the Spanish conquest. It is not certain whether the Indians were aware of them, but if they were, they concealed their knowledge from their conquerors. In 1638, the wife of the governor, the Count of Chinchon, being very ill with malarial fever was cured by the administration of a hitherto unknown remedy, and she took great pains to introduce its use in Europe, and hence the name of the genus which purists spell Chinchona.

The chemistry of these barks was investigated by Dr. Gomes, a Portuguese, who isolated cinchonine in 1816, and in 1820 Pellotier and Caventou isolated quinine, and the alkaloid has since then taken the place of the bulky powdered bark that was formerly employed in medicine. The later investigations into the properties and relations of the various cinchona alkaloids opens up so wide a subject that I will not attempt to go into it, especially as I have very little that is unpublished to add to the stock of knowledge.

From that time the use of Cinchona bark and quinine in medicine steadily increased, and as the collection of the bark was in the hands of ignorant Indians who never thought of planting trees to replace those cut down, district after district was denuded of the trees, and there was every prospect of most inefficient supplies if not of extinction of the genus.

In British India there was not only a great demand for quinine, but climatic conditions very similar to those on the Andes, and the Government wisely determined to set about the introduction of the Cinchona into the country. It was no easy matter, the bark collectors arguing rightly enough that if the bark was cultivated elsewhere their occupation would be gone, and any one who was even suspected of an attempt to carry off plants or seeds went in peril of his life. Undeterred by these difficulties, Sir Clements Markham and his coadjutors arranged expeditions into the districts from which the most valuable species were procured, and after adventures, far more interesting than those of a novel, succeeded in bringing home plants in Wardian cans and seeds of various species, specially of the *Succirubra* and *Officinalis*.

It all sounds very easy, but to get the plants alive to the coast, to keep them alive on the voyage to England, and again through the Red Sea was a triumph of skill and patience. When they reached India, they were cultivated,

with infinite care and skill at Darjiling, and on the Himalayas. At the former place, the Government were fortunate in securing the services of a Scotchman named MacIvor, who nursed them as only a Scotch gardener can. The cultivation prospered and spread to other districts of India and Ceylon, and for 10 or 15 years the greater part of the quinine supply of the world was obtained from India and Ceylon.

The cultivation of these barks under such skilful management has thrown light on many questions as to the formation of alkaloids in these barks. Samples of the wood and leaves of the trees were carefully examined for the alkaloid, but none was found in either; it seems therefore, that the elaboration of the alkaloids takes place solely in the downward course of the sap. Further, that the percentage of alkaloid constantly increases in the bark from the twigs to the ground, and certainly in the less flourishing trees the root bark is richer still. Another curious point is shown by such analyses, namely, that the root alkaloid invariably contains more of the dextrogyrate alkaloids, quinidin and cinchonine, than the bark of the same tree above the ground.

Another point of great interest that has been made very clear is, that the more flourishing a tree is the more alkaloid it will produce, and the result of cultivation has been to produce bark yielding 10 per cent. or even more of alkaloid; this is three or four times as much as was found in the average wild barks of commerce. I remember that the first 5 per cent. bark I tested, astonished me so much that I at once repeated the analysis, thinking that my weighings must have been wrong. To obtain such results as these, however, it is necessary to have the best varieties as well as healthy trees. The yield from trees growing side by side, all from the same cultivation, of the same seed, in the same soil differs very widely, and a great number of analyses of individual trees showed by the irregular incidence of good and bad tests that the variation must be in the trees and not in the conditions of growth.

... By the application of various manures to these trees, it was shown that such manures as increased the apparent vigour of the trees increased their alkaloidal yield, and that for this purpose nitrogenous manures were the best.

I may mention that for the purpose of these analyses, the trees were not cut down, but strips taken from them at the same height above the ground.

As the wood of the trees is of little or no use, a system of bark collection was adopted in India and Ceylon, similar to that by which cork is obtained. In this country, if a portion of the bark is taken from a tree, nature makes an attempt to heal over the wound, but the process is capricious and often fails, but in hot climates, it takes place much more freely, provided always that the cambium is not damaged. Of course, the partial removal of the bark must be longitudinal, ringing a tree will kill it even in the tropics.

The plan successfully introduced by MacIvor was as follows: Incisions were made down the trees about an inch apart and of any convenient length, the enclosed strip being carefully cut across at the top and bottom, the strip was pulled off and dried, a strip of bark was then left untouched, and then another strip taken and so on all round the tree, which was then wrapped round with moss to keep off the sun and air, and in an amazingly short space of time the cambium poured out sap which formed bark all over the wound, not only at the side as we so often see in this country. The next year the strips left on the tree, or a portion of them, could be similarly treated, and the second or third year the renewed bark could be taken off and the same process of healing would take place. A similar process has also been treated by cutting shavings off the trees with a spokeshave, but though involving much less labour, it is less effectual, as it is most difficult to cut deeply enough into the bark to ensure the process of renewal without damaging the cambium.

The renewed bark gives very interesting results, it is in the first place richer in alkaloid; this is not surprising, as it has always been found that the alkaloids were chiefly contained in the cellular tissue of the bark, not in the fibrous portion. In some barks, these two structures

are very distinct, and there is no difficulty in cutting them apart. The renewed bark shows little or no sign of fibrous growth, and is almost entirely cellular.

But not only is the quantity of alkaloid greater, but the quality is very different. The species which lend themselves best to this treatment are the *Succirubra* and *Officinalis*; both these and especially the *Succirubra* yield, from the natural bark, large percentages of cinchonidine. In the renewed bark the proportion of cinchonidine is very much diminished as compared with the quinine, sometimes almost disappearing. This result is curiously different from the changes in the relative proportion of alkaloid found in the root; there the dextrogyrate alkaloids increase as against the levogyrate, here the less oxydised levogyrate alkaloid increases as against the more oxydised. It is difficult to imagine that one changes into the other, if Pasteur's formula were correct, and the difference were only in the oxygen, that might be, but it is evident that the difference is much more fundamental.

Another point of interest was the study of hybrids. The inflorescence of the cinchonas lends itself greatly to hybridisation owing to the fact that the flowers, though having both stamens and petals are of two forms, sometimes the one, sometimes the other of the organs being prominent, and thus fertilisation must take place from another flower by the help of insects.

Many hybrids were produced, but it is unfortunate that no accurate records are available of the exact circumstances of the crossing. It was difficult if not impossible to learn which species was the seed bearer. One hybrid, known as "Robusta," was specially interesting, its growth was even more luxuriant than that of the parent *Succirubra*, while the yield and purity of the quinine approximated to fine Calisaya.

A great deal more would doubtless have been learned but for the fact, disastrous for British India and Ceylon, that the cultivation of cinchona in those regions ceased to be profitable. In old days the unit of price, i.e., the cost of each percentage of quinine in a pound of bark varied from 8d. to 2s. At 6d. the cultivation in the British plantations was splendidly profitable, but the Indian Government was not the only one that perceived this importance of cinchona cultivation.

The Dutch had, early on, rightly guessed that Java afforded an ideal home for the cultivation of cinchona, and great efforts were made to obtain plants or seed. At first, though the plants were obtained they were, by accident or on purpose, a collection of species very interesting no doubt to the quinologist, but utterly valueless as a source of valuable alkaloid.

At last, an English merchant named Ledger, living on the West Coast of America, obtained, by the help of an Indian named Manuel, a packet of seeds, largely from one magnificent tree; when Manuel went home again the cascerilleros found out what he had done and underrated him.

These seeds were sold by Ledger, half to British India and half to the Dutch Government; he received, I think, £50 from each, all of which he gave to the widow of poor Manuel. The British half was somehow or other mismanaged, and at any rate no success was obtained in the cultivation. The Java portion gave very different results.

In the skilful hands of the managers of the Government gardens the plants thrived wonderfully, and were managed with most admirable skill. The barks of individual trees were analysed, and only those which gave high tests were allowed to flower; the seed from these was cultivated in spots far away from other plantations, and the same weeding out of the inferior plants repeated. The result has been wonderful. The richest bark from South America, such as, no doubt, Ledger's seed came from, yielded up to 4 per cent. of quinine alkaloid; we now find in the Amsterdam sales, whole parcels of bark giving 10 per cent. of quinine alkaloid. Where the plant finds room for it, it is hard to guess. It is a curious question—what use, if any, the alkaloid is to the life of the tree. The alkaloid is only produced in favourable soil and environments, and at high elevations. The trees may apparently flourish at low elevations or in hot houses, but in those circumstances the yield of alkaloid is very

small. It is clear that the fault is in the circumstances not in the trees, for some of the richest officialis bark in the Nilgiris was obtained from trees which were the offspring of trees grown from cuttings sent out by my uncle, J. E. Howard, F.R.S., from plants grown in England. These mother plants out-grow his hot houses, and had to be cut down; their bark contained but little quinine.

The wonderful strain of Calisaya, called after Ledger Ledgeriana, was eagerly cultivated with all the Dutch skill in gardening, and now the yield of Ledgeriana bark from Java is about 12,000,000 lb. per annum. I hear of dividends of 60 per cent. from plantations in Java, and Ledger got nothing.

"Sic vos non vobis festis amtra boves."

In the rich deep soil of Java, the trees flourish marvelously, and sprout so freely from the root that coppicing, instead of the laborious process of renewing, is universally adopted. In six years the plantation begins to yield, and may go on for many years.

Now, as it is cheaper to grow 6 to 10 per cent. bark in Java than 2 to 5 per cent. bark in British India, it is not wonderful that the English planters were beaten out of the field, and the Dutch planters, by growing more than the market could possibly stand, and recklessly competing in their efforts to sell, got the price down to 0.4 of a penny per unit. They were profoundly convinced of the wickedness of the quinine manufacturers of the world, but learned their lesson, and by allowing the demand to overtake the supplies, got the unit up to 2d. Over production again followed, and the price is down to 1d. and falling still.

A good deal of "hybrid" bark is sent from Java without very clear intimation of its origin, it gives a sporting interest to the analysis, as one never knows if it will turn out as calisaya or succirubra, and bark is also sent as succirubra which from its test must be robusta. Another very interesting study is given us by the grafted bark of which a good deal has been grown, Ledgeriana, being grafted on a succirubra stock; this "enten baast" generally gives excellent tests, but lately some of the plantations seem to have worn out, and the root bark has been sent over; it is most interesting to find that this gives exactly the test of succirubra root, and "enten wortel" and "enten baast" are as different as the bark of the stock and the bark of the graft originally were. This shows that there is no transference of the alkaloid from above downwards; that the descending sap cannot carry the alkaloid as such, but that the stem and the root each elaborate after their own kind.

The success of the Dutch in knocking out all their rivals, and it must have required the doggedness of a Hollander to hold on, even in Java at 2½ cents, has prevented other plantations of cultivated bark having the success they deserve.

We receive, however, cultivated calisaya from the Andes, and some wonderful cultivated "soft Columbian bark" has lately been brought to London. The cultivation in Jamaica is only a question of price, and we get the very richest Succirubra bark from West Africa, but as people do not take quinine for enjoyment because it is cheap, but only when they want it, the supply now seems to have but little to do with the demand. . . . It is true that the reduction in price from 10s. to 10d. has increased the consumption to about ten times what it was 40 years ago, but now it is difficult to imagine that anyone now goes without quinine on account of its price.

The synthesis of quinine has always been hitherto an unattainable aim. It has been frequently attempted, and I believe that to one such attempt we owe the invention of aniline dyes; even the change from one alkaloid to another has only been effected in one case. It used to have a pecuniary as well as a scientific attraction, but, from the commercial standpoint, can we hope to beat nature with her synthesis of 10 per cent. Ledgeriana?

DISCUSSION.

Dr. DIVERS said he had much pleasure in congratulating Mr. Howard on the discourse he had given on a subject in which he was such an expert. He could confirm from personal knowledge the statement that Dr. Perkin

was indeed seeking the synthetical formation of quinine when he discovered the coal-tar colours.

Mr. R. A. ROBINSON said he had noticed that the Medical Council recognised Succirubra as the only bark now used in pharmacy, but he hoped the culture of the other barks in India was not ruined. If it was bought by the unit, and could be grown cheaply, he hoped it could still be cultivated and used by manufacturers, although it could not compete with the richer bark which came from Java. He entirely agreed with Mr. Howard that there was a point at which it was no good producing a thing more and more cheaply. A thing might be too cheap, and hence not valued. If it were the fact that quinine could be bought in India, where it was urgently needed, at such a low price that the poorest natives could have the benefit of it, its cultivation should not be pressed beyond a certain point, because there was no benefit in producing larger quantities.

Mr. HANBURY said he was much interested in what the author had said about the readiness with which various species of cinchona hybridised. He should like to ask whether it was not usual to find much greater strength in the trees which were hybridised than in the original species when they were transplanted in a different country. The plants he was interested in himself, when hybridised, were far more vigorous than the imported species. It was difficult to keep the imported species as good as they were when they first came over; whereas the hybrids grew larger and larger, and became far finer plants than either of the parents. He should like to know whether it was the hybrids formed in these new countries, such as Java, or the transplanted species that gave the best results?

Mr. E. M. HOLMES said he understood that the renewed bark was richer in quinine than the ordinary bark. And he believed that was even more so in the case of barks which were mossed, but it was found that mossed barks were liable to the attacks of insects, and that process had to be given up, and the bark renewed without moss. He might suggest the possibility that the action of oxygen in the renewed bark might be greater than in the original bark, because it had been stated that when cinchonas were grown at higher elevations, where the air probably contained more oxygen, the proportion of quinine was greater. They had not heard anything about the soil in which cinchonas were grown, and he should like to ask whether it was ferruginous—whether it contained hydrated oxide of iron rather than oxide which was not soluble. The increase in quinine in the root seemed to suggest the greater possibility of oxidation either by ferrous oxide in the soil or an oxidase in the bark. With regard to hybrids, he imagined it was almost impossible, in the case of trees which were mixed up together, to ascertain which was the male plant and which was the female from which any special hybrid was derived. But what seemed to him of far more importance was this, if they got a good hybrid, it would be possible, he should imagine, to reproduce that by cutting or by grafts near the root instead of depending upon the seeds. He did not know whether that had been attempted by the Dutch, but such a process might lead to the selection of much richer plants. Every horticulturist knew what systematic botanists do not often realise, that among ordinary species you might have "strains"—i.e., some particular individual might present specially advantageous characters. This was probably the same with cinchonas, and those particular individuals of the so-called species or hybrids should be selected for cultivation. He did not hear Mr. Howard say whether the low price of quinine was due in large measure, as he had heard, to the introduction of immense quantities of the *Zeuprea* bark into this country, which, being cheaper than cinchona bark, lowered the price of the alkaloid very considerably. Cinchona is now cultivated very largely in Bolivia, so that, even if they had an extra supply from Java, there would still be the Bolivian supply to supplement it. One could not but regret that the Indian Government had not succeeded with Mr. Ledger's seeds as the Dutch had.

Dr. PASSMORE said Mr. Howard would forgive him if he claimed for an English chemist, Dr. Paul, the honour of having separated the two constituents of homo quinine,

namely, quinine and cupine. That was done in his laboratory some few weeks before Dr. Hesse, who received the Hanbury gold medal from the Pharmaceutical Society for his alkaloidal work, did the same; but Dr. Hesse went further, and showed that cupine, the second alkaloid of the homoquinine, stood in the same relation to quinine as a phenol did to its simple ether; so that by methylation of cupine quinine could be obtained. Although chemists had so far failed to produce quinine synthetically, nevertheless the study of organic chemistry relating to the constitution of the alkaloids had produced a wonderful number of other substances of importance in the medical world. Antipyrin, for example, was an enormous success. It was supposed at one time that it would eclipse quinine entirely, but it had lived alongside it. There was only one cinchona alkaloid which was worth mentioning now, and that was cinchonamine, which had an interest to chemists because at the time it was discovered it was pointed out that it was an excellent reagent for nitric acid.

Dr. Power said the history of the cinchonas was a remarkable one, and, although it included some traditions, there was much of substantial fact, for it presented a marvellous record of travel and exploration, in which occurred the names of many distinguished persons, such as those of Humboldt, at the beginning of the past century, and Sir Clements Markham, at a later period. The subject was also one which had afforded a most fruitful field for botanical and chemical investigation. In the long roll of illustrious names connected with the cinchonas, that of Howard occupied a prominent and worthy place. He recalled the fact that Mr. John Eliot Howard had not only published a valuable work, entitled, "Quinology of the East Indian Plantations," but that he had rendered a further most important service to quinological science. It was recorded, for example, that the work of the Peruvian botanists, Ruiz and Pavon, designated as "Nueva Quinologia," which was written between 1821 and 1826, but not then published, was entirely lost sight of for a period of over thirty years. Through a fortunate circumstance, however, it came into the hands of Mr. John Eliot Howard, who not only published it, but embellished it with 27 plates, most of them made from the original drawings of Pavon, lying in the herbarium at Madrid.

Dr. H. A. D. JOWETT said the exact constitution of quinine was not yet determined, and it appeared to him that this ought to be known before anything could be said about its synthesis. But, with the remarkable instance of the synthesis of Indigo before them, it was not too much to hope that, at some time, even with the low price of quinine, they would be independent of the natural product, and be able to produce the alkaloid in the laboratory synthetically.

Sir GEORGE WATT and Mr. P. MACLEWAN also contributed to the discussion.

Mr. DAVID HOWARD, in reply, said an enormous quantity of quinine was used for sub-cutaneous injection, the acid hydrochloride being the usual salt now used. He fancied it was much less irritating than the acid sulphate. With regard to the supply of *Succirubra* bark for pharmacy, he did not think there was much fear; many druggists, Italian druggists especially, would give enormous prices for really inferior bark if it only had the right appearance of lichen on it. The only difficulty they found was that the Pharmacopœia provided a maximum in alkaloid which was much below the average of the rich cultivated *Succirubra* bark. The Pharmacopœia prescribed 6 per cent. of alkaloids, and if you gave 10 per cent. it would be rather a heavy dose for the patient. For pharmacy it was no doubt one of the finest, if not the finest, bark there was, and the Dutch were growing it very freely. Owing to the great production of bark, the wholesale price of German quinine was now 8½d. an ounce. He wished he knew more about hybrids; there were a great many produced, and they seemed to thrive. What was commonly known as a hybrid in Java was a hybrid of the *Calisaya*. They called them all hybrids, and when a bark was marked "hybrid" one could not foretell whether it was going to turn out a *Succirubra* or *Ledgeriana*. But the grafted bark interested him, because of the very

great purity of the alkaloids of graft, and the unmistakable original condition of the root. As to the soil, he only knew it was said to be very rich and black. Probably it was ferruginous, and that might have something to do with the production of alkaloids. The question of mossed bark and renewed bark was exceedingly interesting. The mossed bark was chiefly the intermediate strip which was left when the bark was taken off, and it was then covered with moss to keep the moisture from evaporating so that the renewed growth might take place. The mossed bark was quite as rich as the renewed bark. Apparently the stimulating process had done it good. It was rarely richer, but the mossed portion continued to contain the same proportion of alkaloids as before. The *Cuprea* bark undoubtedly brought down the price a good deal, as low as 6d. a unit. Then came in the flood of Ceylon bark, and then Java, and it ceased to pay.

A NEW METHOD FOR THE QUANTITATIVE DETERMINATION OF ACETONE.*

BY S. J. M. AULD, PH.D., A.I.C.

The content of acetone in wood-spirit and crude acetone is frequently required for technical purposes by varnish makers, wood distillers and others.

The methods at present employed for the quantitative determination of acetone are on the whole unsatisfactory, the conversion of acetone into iodoform being generally employed for its estimation. Either the iodoform is directly weighed after extraction with ether as in the method generally attributed to Kramer, or the excess of iodine is titrated with sodium thiosulphate in presence of starch. A third method devised by Squibb, and improved by Kebler, gives satisfactory results, but is exceedingly cumbersome, no less than five special solutions being required. (See this J., 1897, 168, 569.)

The use of iodoform for quantitative work is open to several objections, especially in the older and more general method of procedure in which it is itself weighed. Iodoform is very volatile, some loss by evaporation being caused even at ordinary temperatures. It is also decomposed to a certain extent by the oxygen of the atmosphere when exposed to sunlight, with the formation of iodine, carbon dioxide and water. This action can frequently be observed when estimating acetone by the gravimetric method, the residue left after complete evaporation of the ethereal solution very often having a distinctly brown shade.

A volumetric method for the estimation of acetone has been worked out depending on the formation of bromoform and its subsequent hydrolysis with alcoholic potash. The hydrolysis is generally expressed as follows:—

The residual potassium bromide is estimated by means of standard silver nitrate solution.

Bromoform is specially suitable for this purpose for several reasons. It is very readily formed by the action of bromine and potash on acetone, and, although very volatile in steam, it is not liable to loss due to its own evaporation. Further, its high molecular weight and large percentage of bromine conduce to accurate results, 58 gra. of acetone being responsible for the formation of 357 gra. of potassium bromide.

The method of carrying out the analysis is as follows:—

* Taken as read.

† M. Klar "Die Holzverkohlung," 1904.

A known quantity of the solution to be tested, containing acetone to the extent of 0.1 to 0.2 grm., is pipetted into a 500 c.c. round bottom flask, diluted with a little water, and mixed with 20—30 c.c. of a 10 per cent. solution of caustic potash. The flask is connected with a long reflux condenser, and is also fitted with a dropping funnel containing a solution of bromine in potassium bromide (200 grms. of bromine and 250 grms. of potassium bromide to 1 litre of water). The bromine solution is allowed to flow into the mixture until it has acquired a faint yellow tinge, the flask and its contents being then heated on the water-bath at about 70° C. for half an hour. Bromine solution is added drop by drop until the slight coloration is permanent, excess of bromine being got rid of by boiling for a minute or two with a little more caustic potash. The mixture is then distilled until the distillate is free from bromoform, halogen being tested for in the usual manner. Water is added to the contents of the flask if necessary. It may be here observed that no acetone can be detected in the distillate by means of the mercuric oxide test, and free bromine is also absent. The condenser having been washed out with a little alcohol in order to remove any traces of bromoform which may have collected, the distillate and washings are mixed with 50 c.c. of alcohol and sufficient solid caustic potash to make an approximately 10 per cent. solution. The mixture is then heated on the water-bath under a reflux condenser until the bromoform is completely decomposed. This generally occupies about three-quarters of an hour. The liquid is allowed to cool, evaporated to smaller bulk if necessary, and exactly neutralised with dilute nitric acid. It is then diluted with water to 500 c.c., and aliquot parts titrated with N/10 silver nitrate solution, using potassium chromate as an indicator. 240 parts of bromine correspond to 58 parts of acetone.

The complete analysis can be performed in 1½—2 hours. Some of the results obtained by this method are quoted below:—

1. Three c.c. of a solution containing 9.61 per cent. acetone gave 1.7850 gr. KBr. Acetone found = 9.66 per cent.

2. Ten c.c. of a solution containing 0.96 per cent. acetone gave 0.5847 gr. KBr. Acetone found = 0.95 per cent.

3. 0.5 c.c. of a solution containing 34.2 per cent. acetone gave 1.0460 gr. KBr. Acetone found = 33.8 per cent.

The method is suitable for the estimation of acetone in wood spirit, the spirit being diluted to 10 times its volume and 5 c.c. of this solution employed for the determination. Results of the same standard of exactness as those quoted above can be obtained.

The formation of carbon tetrabromide from the bromoform cannot be urged against the process, as by the above procedure any appreciable excess of free bromine is avoided. It is imperative that the bromine employed should be pure, as crude bromine frequently contains bromoform.

‡ This stronger solution was diluted to ten times its volume and 5 c.c. of this taken for the estimation.

Manchester Section.

Meeting held at Manchester on Friday, January 5th, 1906.

DR. J. H. BAILEY IN THE CHAIR.

CHEMICAL AND PHYSICAL VALUATIONS OF SOME CLAYS AND SHALES, FOR BRICK-MAKING, CHIEFLY FROM EAST CHESHIRE.

BY DR. E. A. WAGSTAFFE, M.Sc., F.I.C.

In England the scientific study of the uses and characteristics of clays, except the materials used in the manufacture of china and ordinary table and toilet ware, is just beginning to be appreciated by the practical man. A few of the results of an extensive series of experiments made by the writer, on clays and shales from the districts near Manchester, may therefore be of interest to clay workers.

The writer has made a special study of the shales from the middle and lower coal measures of East Cheshire, a district which, though hitherto neglected by the high class brick, tile, and terra cotta maker, abounds in a great variety of most excellent raw material.

For convenience of reference the clays and shales are numbered. The one numbered 3 is a hard West Bromwich marl, and is given as a standard of comparison for engineering bricks.

No. 1 is a surface clay from Marple. In appearance it is of a sandy clay colour, containing small lumps of lime.

No. 2 is a clay supplied by Messrs. Peter Bailey and Sons, Heaton Mersey, used for making common bricks.

No. 3 is the West Bromwich marl. In appearance it is of a reddish clay colour, and was obtained in a plastic condition ready for use.

No. 4 is a shale from the top of Kerridge. It is of a dark grey colour, and very hard. It occurs in seams among the rough rock overlying a bed of fine ashlar sandstone in the upper strata of the lower coal measures.

No. 5 is a shale from Pingot Colliery, between Birch Vale and New Mills. It is almost black in colour and occurs in solid masses in the lower coal measure series. It is very hard.

No. 6 is a surface shale from Wigan. In colour it is inclined to yellow, and is hard.

No. 7 is the shale found below the preceding one at Wigan. It is the colour of light grey stone, and is very hard.

No. 8 is a shale from Endon Quarry. In appearance it is of a reddish clay colour, and is fairly hard.

No. 9—this shale is found in a ravine at Middlewood in the middle coal measure.

No. 10 is a shale found in East Cheshire, and occurs in black hard masses.

The clays and shales were first submitted to analysis. To this end they were ground very fine, and dried at 100° C. Nos. 1, 2 and 3 being received in a plastic condition, were first dried, and then carefully ground to a fine impalpable powder, and dried at 100° C. The analyses were made upon the clays and shales dried at 100° C. The total constituents of the clays and shales were determined in the usual way. The composition of the clays and shales, or the rational analysis, was determined by the method depending upon the fact that kaolin is more or less dissolved by long digestion with hot concentrated sulphuric acid. The sand and felspar are determined in the insoluble residue.

Silica and Bases.

For the purpose of studying the effect of various temperatures (1000°—1250° C.) upon the clays and shales, they are made into small briquettes, measuring $1\frac{1}{2}$ in. by 1 in. by $\frac{1}{2}$ in. The shales are ground to a fine powder, mixed with water until fairly plastic, and then moulded with a moderately strong pressure, so that, on turning out, the briquettes have perfectly sharp edges. The briquettes are carefully dried at 100° C., removed to a desiccator and allowed to cool, when they are weighed and accurately measured. They are re-heated at 100° C. until the weight is constant. The briquettes are next burnt at the following temperatures in succession, viz., 1000° C., 1050° C., 1100° C., 1150° C., 1200° C., and 1250° C. Weighings, measurements and observations are taken at each of these temperatures. The measurements of the briquettes are also checked by ascertaining their volume, by displacement of water.

The burning of the briquettes is effected in muffle furnaces. A temperature of 1000° C. can easily be reached in an ordinary muffle furnace, provided the gas supply is more than sufficient to work the furnace at its full power.

For temperatures above this, the writer has found that Fletcher, Russell and Co.'s gas muffle furnace provided with air blast gives excellent results. It is simple to work and easy to regulate to any desired temperature from 1000°—1400° C. For ascertaining and controlling the temperature, the writer uses Seger cones, so that all temperatures mentioned in this paper are those which correspond with the cones used.

The briquettes, dried at 100° C., are placed in the furnace, and heated gradually at first. The heat is then increased until a temperature of 1000° C. is attained. They are burnt for a considerable time at this temperature. The briquettes are allowed to cool in the furnace, weighed, measured, and observations taken of colour, density, &c. The briquettes are then burnt at the higher temperatures in succession, noting weighings, measurements, &c., at each temperature.

The results of the loss in weight sustained by the clays and shales, dried at 100° C., at the different temperatures, and their shrinkage, i.e., the percentage loss in volume, are collated in the two following tables:—

The specific gravity and porosity of bricks are of some importance. These determinations were made of briquettes, obtained from the clays and shales by burning at the three following temperatures, viz., 1000° C., 1100° C., and 1200° C.

As bricks are porous bodies, it is necessary to take into account this pore space in determining the specific gravity. If this pore space is not taken into account in calculating the specific gravity, we obtain that quantity defined by Seger as volume weight, viz., the ratio between the weight and the total volume of the body inclusive of the pores.

The determinations were made as follows:—

The weight of the briquette having been ascertained, the briquette was soaked in water for 24 hours, taken out, and the surface water removed with a dry cloth. The increase in weight gives the amount of water absorbed by the briquette, i.e., the amount that fills the pore spaces. The volume of the briquette is determined by displacement

of water. The volume may also be determined by measurement, provided the briquette has not suffered any unequal contraction, whereby its shape has become distorted.

Then if the weight of the briquette in grms. is w , and the increase in weight due to absorption of water is t , and the volume in c.c. displaced when water saturated is v ,

$$\text{The Specific Gravity} = \frac{w}{(v-t)}$$

$$\text{The Volume Weight} = \frac{w}{v}$$

$$\text{Porosity} \dots = \frac{100 \times t}{w}$$

The results of these determinations are collated in the following tables:—

Specific Gravity of Briquettes.

With respect to the suitability of these clays and shales for brickmaking, No. 2 is undoubtedly a good clay for common bricks, as is also No. 1, although the bricks are somewhat friable. Most of the clays and shales do not withstand the temperature at which a good engineering brick is obtained, the exception, besides No. 3, being No. 8, from which an excellent engineering brick can be obtained. No. 10, might, with some manipulation, be employed in the manufacture of fire bricks, as the colour is good and the shale withstands the highest temperature reached in these experiments.

The temperature at which the clays and shales melt, was determined by comparison with the melting points of Seger cones. For this purpose, each clay is made into a plastic mass with water, and moulded into the form of a small cone or pyramid. The cones are then carefully dried at 100° C. before being burnt with the Seger cones.

The following temperatures were obtained:—

Melting Points of the Clays and Shales.

1.	2.	3.	4.	5.	6.	7.	8.	9.	10.
1250° C.	1160° C.	1410° C.	1430° C.	1370° C.	1120° C.	1270° C.	—	1430° C.	—

The refractoriness of clays for brick and terra-cotta is an important point. It may be determined directly, as above, by ascertaining the temperature at which the clay begins to fuse. Refractoriness may also be judged from a survey of the chemical data. Thus, the silicates of lime, magnesia, and alumina are practically infusible; on the other hand, those of soda, potash, and iron are readily fusible. If lime, iron, or alkalis be added to the infusible silicates in calculated quantity, double silicates are formed, which also are readily fusible. Hence, refractoriness of clays depends chiefly on the percentage of silica and alumina, and is influenced by the presence of alkalis, iron, lime, and magnesia in the order mentioned. It must be noted, however, that if any of these bodies be in excess, the fusibility of the clay is not necessarily lowered, as, for instance, excess of soda would set free lime and magnesia, which themselves are infusible. A comparison of the chemical composition of the clays and shales from this point of view with the actual melting points as determined is not without interest, as showing relationship of composition and refractory character. The melting point of No. 6 is 1120° C. This clay contains over 30 per cent. oxide of iron. No. 2 fuses at 1160° C., the easy fusibility of this clay is evidently due to the low percentage of alumina, and high percentage of alkalis, lime, and magnesia. Nos. 1 and 7 fuse at 1250° C. and 1270° C. respectively. The high percentage of lime, magnesia and iron, and the low percentage of alumina account for the

fusibility. The higher refractoriness of No. 9 is no doubt due to low percentage of lime and magnesia. The remaining clays all contain over 22 per cent. of alumina, and all are highly refractory.

Dr. WAOSTAFFE, in reply to several questions, said the experiments referred to in the paper had been carried out on a small scale in the laboratory, and he could not say that the same results would be obtained on a large working scale. He did not consider the length of time taken in obtaining the melting point of the clays and shales was a material point, and he had not estimated the carbon and sulphur. The change in specific gravity, was undoubtedly due to shrinkage in volume and increase in weight. Porosity was tested for by immersing the bricks for 24 hours in water, leaving one-eighth of an inch above the surface.

DR. RUSSELL W. MOORE IN THE CHAIR.

NEW PROCESS OF PUERING OR BATING HIDES AND SKINS.

BY DR. ALLEN ROGERS.

The process to be described is covered by U.S. Pat., No. 798,293, by Francis J. Oakes, of New York City (this J. 1905, 1023).

In working with the Oakes' process the skins or hides are washed, limed, unhaired, and washed again. A bath is now prepared at a temperature of from 95°—100° F., consisting of 5 per cent. of glucose syrup, and 1 per cent. of sulphur, computed on the weight of the skins or hides, and about 1 lb. of yeast for every 1000 lb. treated. Having prepared the bath in this manner it is allowed to stand about 24 hours to secure a definite fermentation. At the end of this time the temperature is raised to 100°—105° F., and the hides or skins introduced. In order to have a continuous bath, however, one half the original amount of sulphur, glucose, and yeast are added at the

same time. In working this process it is not necessary to keep the skins or hides in constant motion, but only to move them from time to time in order to secure uniformity of action, once an hour being sufficient. By this method of treatment heavy bull or cow hides will be free from lime, and in a soft and open condition at the end of eight hours; while lighter skins will require a proportionately shorter period. On removing the pack the temperature of the bath may be raised, and after introducing one half the original quantity of sulphur, glucose and yeast, another pack may be treated, so making it possible to work two packs each day in the same vat if desired. It will be understood that a continuous bath would, in time, become too concentrated from solutions of calcium compounds, and thus prevent or retard fermentation. This difficulty, however, is obviated by drawing off half of the solution each and every time after treatment of the second pack.

The hides or skins as they are removed from the bath show no trace of lime with phenolphthalein. They are soft and open, and have a smooth silky grain. As there is nothing in this treatment to cause putrefaction, there is, consequently, no loss of hide substance, and, furthermore, as all of the lime has been neutralised they do not require a drench or pickle, but after washing are ready for the tan, regardless whether it be vegetable or mineral in character.

From a chemical point of view it is somewhat difficult to express all of the reactions taking place in the bath, although by careful observation and thought certain conclusions are apparent. Thus when the bath is first prepared it is neutral in reaction, and after standing gradually assumes a slight acid condition. On introducing the hides or skins it becomes alkaline, due to diffusion of the lime. After standing a short time, however, it becomes neutral again, and remains thus until the skins are in a perfect condition, when a slight acid reaction is observed. These changes taking place are caused by the fermentation of the glucose, which generates carbon dioxide and alcohol; and owing to the presence of sulphur a quantity of hydrogen sulphide is produced, which in its nascent condition combines with the alcohol to form mercaptans, which in their turn are slowly oxidised to thio-acids. These mercaptans and thio-acids, being of a weak acid character, act in conjunction with any excess of hydrogen sulphide, upon the calcium hydroxide, or other compounds of calcium, converting them into a soluble condition, in which they are readily removed by diffusion. Thus, when the lime is all neutralised the bath becomes acid in reaction, and in this way serves as an indicator of the completion of the operation. It is not necessary, however, to remove the hides or skins as soon as the acid condition is secured, as the products formed and the excess of acid do not dissolve the gelatin; and as there is no putrefaction there can be no loss of hide substance, or depletion, which assertion has been proven by practical demonstrations, and the value of the process established beyond a doubt.

precipitation decreases to a corresponding extent the value of the finished glue.

The present paper attempts, *inter alia*, to prove this synthetically. It will be shown that consistency is very largely influenced by the presence of peptones. Further experiments have been undertaken with the object of (1) Throwing light upon the cause and remedy of foaming in glue; (2) obtaining some idea of the effect of some of the impurities commonly present in glue on both the foaming capacity and the consistency of the jelly.

In making these experiments, foaming power and consistency were chosen as special tests, since they are two very important properties to which a manufacturer must attend. A good glue should give a minimum foam with a maximum strength, two qualities which by no means go hand in hand. Many strong glues have high foam figures, although most bad ones have, also. Thus it will be shown that over boiling, which, as we have before proved, causes peptonisation and corresponding loss of consistency, invariably increases the foaming power of a glue. The results obtained prove that certain classes of bodies considerably affect both the foaming capacity and the strength of a glue, and that care in manufacture directed to the elimination of these deleterious impurities would result in much improvement in commercial glues. While considerable attention has been called to the evolution of methods of testing glue, little has been done to elucidate which of the constituents of the glue affect these properties prejudicially or otherwise, although it is obvious that such an investigation must be of great value. Users of glue and size are continually complaining of the foaming nuisance. A glue which foams badly is of little use for making joints, especially if applied by means of a rotatory brush, since the air bubbles which it contains render the joint valueless. In the dressing of fabrics, a foaming glue causes an uneven deposit and tends to produce films, which block the holes in the case of a net, and are difficult to remove. The value of a high consistency is too well known to need emphasis.

Consistency.—This was measured in a special form of apparatus, which it is hoped will be made the subject of a further communication, since the method appears capable of considerable development. In brief, it consists in measuring the time taken by perfectly symmetrical spheres to fall through a column of the substance under examination.

Foaming.—The literature on this subject may be summed up in the statement that a 10 per cent. solution is employed in testing foaming capacity, and that glues give from half to eight inches of foam. The method used in testing is, of course, immaterial when comparative results only are desired, but those at present employed are so varied that there is little chance of close agreement.

The method described below is free from this objection, and the necessity for some standard form of test is shown, by the fact that the amount of foam given by a solution of glue is dependent upon—(1) the height of liquid in the tube; (2) the diameter of the tube; (3) the temperature of the solution, and, to a less extent, the time and method of testing.

The following experiments illustrate these points:—

(1) Varying quantities of the same solution were shaken in identical tubes, the results being shown in Table A, indicating that height of foam is approximately in proportion to the height of liquid in the tube.

TABLE A.

Influence of Height of Liquid upon the Foam.
Temperature, 60° C.

The effect of varying the diameter of the tube is shown in Table B.

Nottingham Section.

Meeting held at Leicester on Wednesday, November 20th, 1905.

MR. J. M. C. TATON IN THE CHAIR.

CONDITIONS AFFECTING THE FOAMING AND CONSISTENCY OF GLUES.

BY S. R. TROTMAN, M.A., F.I.C., AND J. E. HACKFORD.

In a recent paper (this J., 1904, 1072—1074) we have shown that good and bad glues may be chemically differentiated by means of the ratio between total nitrogen and nitrogen precipitated by zinc sulphate, and that any carelessness in manufacture or selection of materials which increases the quantity of nitrogen incapable of such

TABLE B.
Influence of the Diameter of the Foam Tube upon the Foam Figure.

Volume of Liquid.	Diameter of Tube.	Foam Figure.
25 c.c.	1 cm.	17.5
25 c.c.	2 cms.	7.5

The effect of temperature on the foam figure is considerable, as will be seen in Table C.

70	13.0
80	11.0
90	6.5
100	3.5

The decrease in foam caused by rising temperature is no doubt due to the fact that, as the temperature rises, both viscosity and surface tension become less.

Apparatus Employed in Testing Foam.—A graduated tube, about 70 cm. in length and of such diameter that each division is 1 cm. in length and has a capacity of 1 c.c., is half filled with a solution of the glue to be tested and placed in the water-jacket, the temperature of which may be raised by passing steam into it. The even distribution of the steam is effected by means of a ring at the end of the delivery tube and an overflow is provided. The temperature of the bath is maintained at 60° C., which is a convenient one for glue solutions. After allowing sufficient time for the temperature of the glue solution to reach 60° C., the tube is withdrawn from the bath and its level adjusted by means of the tap till it stands at zero, there being then exactly 25 c.c. of the solution in the tube. The tube is now corked and shaken vigorously for about a minute, replaced in the bath, and the height of the foam read off. The top of the foam is read off, since this is found to be constant with a constant temperature. The line of demarcation between the foam and the liquid is too indistinct to allow of the lower reading being accurately taken. The higher reading is so constant that different operators can always obtain the same figures. Since the foam produced always varies with the temperature, the importance of carrying out the test at a constant temperature is apparent. Prolonged delay often causes hydrolysis and an increased figure.

Foam Figure of Pure Gelatin.—A sample of the purest gelatin containing less than 1 per cent. of peptone and neutral in reaction was precipitated with zinc sulphate as described in a previous paper.* The precipitate was pressed thoroughly to remove zinc sulphate, and then redissolved in water and thrown down by means of alcohol, the latter operation being repeated till the product was almost ash free. It was then dried in a vacuum at a low temperature, after which 1 gram. was dissolved in water and tested as above. The foam figure was found to be 10.5, which may be regarded as the minimum for a generally pure gelatin. Since, however, some glues have a foam figure less than this, it is obvious that certain of the accidental constituents of glue have the power of decreasing the foaming capacity, just as peptones have the power of increasing it. The following experiments were carried out with the object of throwing light upon this point, together with the effect of these impurities on the strength of the jelly formed as measured by the consistency.

(1) *Effect of Peptones.*—100 c.c. of the solution employed contained 1 gram. of albumose and increasing quantities of peptones. The figures show that there is a

continual rise in the foam figure and that this rise is very marked with small quantities of peptones, the result being well shown in the curve (Fig. 2). This is a point of much importance to the manufacturer and confirms the result of a recent paper by us. So far as consistency is concerned, the figures show that small quantities of peptones do not exercise an adverse effect so long as they do not actually replace albumose nitrogen. When, however, the total nitrogen is kept constant and the gelatin gradually replaced by peptone the consistency very rapidly falls to zero.

TABLE 1 (A).
Effect of the Peptones on the Foam Figure of a Glue.

Effect of Over Boiling.—A glue with an original foam figure of 16 was boiled for a varying time and retested. The results show that over boiling must be a large factor in the production of foaming glues.

The following table shows the influence of peptones by hydrolysis on foam figure of a 1 per cent. gelatin solution:

The Effect of Soaps and Fats.—Small quantities of fats decrease the foam, as might be expected, but their addition for this purpose would be inadmissible, since grease is a fatal objection for many of the uses to which glue is put. A small percentage of soap largely decreases the foam figure, but a maximum is soon reached, after which the foam rapidly increases. It is commonly supposed that soaps are the chief cause of foaming, but it is extremely rarely that a glue contains a sufficiently large quantity to show this effect, leaving out of account the fact that the majority of glues are sufficiently acid to decompose a considerable amount of soap. It will be seen from Table 3 that the decomposition products of soaps, such as oleic acid, also reduce the foam figure, although they form a dry scum which would render the glue useless for many purposes.

Effect of Acids.—Upon the assumption that foam is chiefly caused by soaps, the remedy usually recommended is an acid. Table 4 gives the results of an experiment made upon this point. In all cases the required quantity of acid was mixed with the glue solution and allowed to stand over-night. The fall of consistency is only what could be expected, but it is interesting to note that carbolic and salicylic acids, both preservatives, largely reduce the value, while boric acid only does so to a much smaller extent, indicating the superiority of boric acid over the other two as preservatives.

On the other hand, if these acids be added to an already existing foam, carbolic is much more efficient than boric acid, as will be seen from Table 4A. The immediate fall in consistency caused by the acids is, of course, due to hydrolysis with the formation of peptones. Practically all acids are able to peptonise glue, and their presence in more than traces is highly deleterious.

Effect of Suspended Matter.—Finely-divided suspended matter, whether organic or inorganic, considerably affects the foaming power and consistency of a glue. The following experiments were made with solid impurities sometimes found in commercial glues. To a 1 per cent. solution of the glue under examination varying quantities of certain insoluble bodies were added and the mixture well shaken. The foam figure having been noted, the jelly was allowed to set and its consistency measured. The results are given in Table 5.

It may be noted that while plaster of Paris considerably increases the consistency, the hydrated body, $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$

has no effect on it. The experiment also indicates that loaded glues, such as Russian, may be expected to give considerable foam.

Effect of Salts likely to be present in Water.—Table 6 indicates that the quantity of these salts likely to be present in water used in glue making would not be sufficient to affect the quality of the resulting glue, although in large quantities they are able to cause hydrolysis.

DISCUSSION.

Mr. H. S. GARRY said that in dealing with liquids in bulk of, say, 500 to 1000 galls. under vacuum, the foam was always greater in proportion to the quantity of liquor in operation. With regard to Table B, the same remarks applied to liquors foaming *in vacuo*. With regard to Table C, there was a considerable difference in the foaming characteristics of glue in proportion to the temperature at which the glue was originally extracted. In liquors obtained at a low temperature, and which had not been subjected to some peptonisation in extraction, foaming took place very strongly. He thought the paper certainly carried the technical testing of glues a stage further, and was a valuable addition to the literature on the subject. He would like to have seen some attempt, however, to separate the peptones into different classes of glues, as, for instance, bone glues and skin glues. Bone glues invariably foamed to a greater extent than skin glues, and skin glues, subjected to a two hours' extraction, foamed more than skin glues subjected to a six hours' extraction. There was also a distinct increase in consistency in the two-hour extraction glues over the six hours, and a corresponding loss in weight in the six-hour glues. This appeared to be contradictory to some of the statements in the paper. The effect of alkalis on glues was of necessity to reduce the consistency and foaming power. The addition of oils and fats to glue liquors (especially skin glues) did in bulk operations reduce the foaming, but in actual working *in vacuo* appeared to increase the tendency in the initial stages. In evaporating foaming liquors *in vacuo*, where the chief trouble to the manufacturer arose, the principal remedy applied was to increase the temperature at the foaming point, and to decrease it in the liquor; this, in all cases, proved efficacious. For instance, in a vacuum pan having four coils, the top coil would be served with full steam and the lower coils shut off, in which case the foam fell into liquor. In the case of a liquor into which air was admitted, the result was a setting up of a foam, while the admission of liquor at a lower temperature than the vacuum pan would also produce a heavy foam, and once foam has set up in a liquor it remained there. He would be inclined in all cases to regard foams as evidence of decomposition of animal matter in the glue, and thought further researches by the authors would show that the foaming capacity of glue rested almost entirely upon the efficiency of the cleaning and preparing methods employed on the material before extraction.

Mr. L. ARCHBUTT thought that the method of measuring foam employed by the authors would be improved by agitation by means of a current of air. The application of the principle of allowing symmetrical spheres to drop through a vertical column had been mentioned as applicable to the measurement of viscosities; but he felt bound to protest against the multiplication of instruments for the measurement of viscosities, none of which in his opinion offered many advantages over a burette form of viscosimeter, and many of which lacked simplicity of construction and manipulation.

Mr. H. J. WATSON wrote:—"Foaming glue is a subject very imperfectly understood; it is one upon which I have worked, and have already published a pamphlet which only differs from that of the authors in some minor details. The following are the particulars of my test, published four months ago in a technical trade journal:—

The glue to be examined is broken up in an iron mortar, over which a cover is placed to prevent glue from flying about; 5 grms. are weighed out, and put into a beaker of 100 to 150 c.c. capacity; 40 c.c. of water are then poured over the glue, and allowed to soak several hours, preferably overnight. The beaker is then placed in a water-bath heated to about 130° F. When completely melted the solution is poured into a stoppered measuring jar graduated to 100 c.c., and about 2½ cm. diameter. The volume in the jar will be about 45 c.c.; this is made up to 50 c.c. by washing out the beaker with hot water. The temperature of the solution of glue will now be about 120° F. The stopper is inserted, and the jar shaken vigorously for a few seconds or until no more foam is produced. The jar is then allowed to stand for a

few minutes. It will be noticed that the foam gradually collects upon the top of solution. As soon as the height of the solution has reached 45 c.c. the height to the top of foam is read, and the difference between 45 and the height to top of foam is taken as c.c. of foam.

"It has been found better to read the height of foam this way than to read the height immediately after shaking, and subtract 50 c.c. In the first place it gives one an idea whether the foam will quickly die away or be permanent, and, secondly, it has been found that the foam-reading is practically the same, because taking the reading from the top of the solution at 45 c.c. makes up for any shrinkage in volume of foam. With some glues the height to top of solution reaches the 45 c.c. mark quicker than others; this is an indication that the foam will die away quicker, which is also an important point to know.

"This test has been used on a considerable number of samples, and the following table is a comparison of glues from different sources:—

Source.	Quality.	Colour.	Grms. taken.	Made up to c.c.	Top of foam c.c.	Top of Soln c.c.	c.c. Foam

"I can confirm the authors' conclusions with regard to over-boiling. Acid and alkali, in my own experiments, do not appear to influence the amount of foam produced. There is one important factor, not touched upon by the authors, viz., the source of the glue. The cleansing of the raw material from foreign matter is a very important factor, and if neglected it matters little how much care be taken with the boiling operations."

Mr. S. R. TROTMAN, in replying, said that the chief difference between the test for foaming which they proposed and that described by Mr. Watson was that their measurements were exactly given and greater care was taken to maintain a constant temperature, and, in fact, to standardise the process; this being essentially a test which required standardisation. It was true that they had not specifically referred in this paper to the cleansing of raw material, but the results, which they had obtained from the introduction of peptones and other degradation products, would point to the importance of so doing, since it did not matter whether the peptone was introduced with the raw material or produced during the manufacture; the effect on the glue was in both cases identical. In their previous paper the authors had already shown that the chief chemical difference between a good and bad glue was the quantity of nitrogen that could not be precipitated by zinc sulphate, and had at the same time drawn attention to the different ways in which the presence of this nitrogen could be accounted for. In his opinion too little attention was paid to the cleansing of raw materials. The removal of loose fragments, and the washing away of the readily soluble constituents from the surface of materials used for glue making, would always reduce the percentage of peptone subsequently found in the manufactured glue, and hence decrease its foaming power, increase its consistency. Of course, it must be understood that all washings thus obtained should be as far as possible recovered. He agreed with Mr. Archbutt

that it would be preferable to agitate by means of air. With reference to the multiplication of viscosimeters, he felt that a method which would do away with the variable head of the liquid and the friction of the orifice would have some distinct advantage.

Meeting held at Derby on Wednesday, January 24th, 1906.

MR. J. M. C. PATON IN THE CHAIR.

RECENT ADVANCES IN THE BACTERIOLOGY OF PUTREFACTION.

BY J. T. WOOD.

To those who have to do with the manufacture of leather the changes which take place in the skin from the time it leaves the animal are of the utmost interest. The most important of these changes is the natural process of decomposition known as putrefaction.

Nineteen hundred years ago Ovid* wrote:—

*Caetera diversis tellus animalia formis
Sponte sua peperit; postquam votus humor ab igne
Percahit Sol, coenunque, udaeque paludes
Intumescere aëta; secundaque semina rerum
Vivaci nutritis solo, seu matris in alvo,
Creverunt, faciemque aliquam cepere morando.*

*Quippe ubi temperiem sensere humorque calorque;
Concipiunt; et ab his oriuntur cuncta duobus.*

Francis Bacon carried this idea a step further, a very natural one for a believer in spontaneous generation, for, if life arose of itself, then by scientific means it should be possible to find out the conditions of this generation and to produce various kinds of life. In his wonderful dream of a college of research ("The New Atlantis," p. 38), Bacon says:—"We make a Number of Kindes, of Serpents, Wormes, Flies, Fishes, of Putrefaction; Whereof some are advanced (in effect) to be Perfect Creatures, like Beastes or Birds; And have Sexes and do Propagate. Neither doe we this by Chance, but wee know before hand, of what Matter and Coniixture, what Kinde of those Creatures will arise."

I need not say that these ideas of the origin of life on the earth are not in accord with modern ones, the theory of spontaneous generation having been completely disproved by the researches of Pasteur, Tyndall and others, though I remark in passing that quite recently certain writers have speculated whether, in the earlier stages of the earth's history, the conditions may have been suitable for the combination of the elements to form living organisms.

You may inquire what this has to do with putrefaction which is the end and destruction of the organism, but the end is also the beginning like the mystical Chrymon of St. Ambrose, no sooner does the work of the higher organism cease than myriads of lower organisms commence their work of splitting it up into its simpler elements, so that it may serve for the making of other bodies of other animals or plants. It has always seemed to me a wonderful thought that the matter of which our body is constructed has served for the building up of the bodies of many other living creatures during an infinity of past time, and will again serve for the making of others "When we have shuffled off this mortal coil."

Putrefaction may be defined as the decomposition of nitrogenous organic matter by living organisms, accompanied by the evolution of malodorous gases. The study

* (Metam. Lib. 1. VIII.) "The earth brought forth of herself the other animals in different shapes, for after her natural moisture had been heated by the fire of the sun and the slime and the wet fens swollen by the heat, the fruitful seeds of things nourished by an enlivening soil as in the womb of a mother, grew, and in continuance of time took some regular shape upon them. . . . For when wet and heat have had a due mixture, they conceive, and all things arise from these two."

of it may be divided into two parts—(1) the biological, (2) the chemical. The first concerns the organisms which break down the proteid molecule either directly or by means of enzymes; the second that of the different products of the action of these organisms. It is extremely difficult to separate these two studies.

Dr. Sims Woodhead (2) gives a concise account of the earliest researches on the organisms causing putrefaction by Leewenhoeck (1692), Pleniz of Vienna, Müller of Copenhagen (1786), Needham (1749), Spallanzani (1769), Schwann (1837), Schroeder and Van Dusch (1854), Tyndall (1870), Lister (1878). These names show that the history of putrefaction proceeds parallel with the evolution of the microscope and the development of the comparatively recent science of bacteriology. I propose to-night briefly to carry it up to the present day.

I need scarcely say that putrefaction is not a specific fermentation like alcoholic or acetic fermentation, but that it is extremely complex. In any putrefying matter, such as gelatin or albumin, a large number of different species of bacteria may be observed as well as monads and infusoria, and in some cases moulds, all of which take part in the process. The first stage is a process of oxidation in the presence of air, in which aerobic bacteria use up the oxygen present and only simple inorganic compounds are formed, carbon dioxide, nitrates and sulphates; this part of the process is generally without odour. The second stage, or true putrefaction, takes place in the absence of oxygen by anaerobic bacteria, and is a process of reduction. It has been shown that there are no bacteria in healthy tissues, and if a muscle or any organ is taken from an animal under antiseptic conditions it may be preserved indefinitely in a sterile vessel to which filtered air has free access. Solid matter is usually liquefied by organisms like *B. liquefaciens magnus*, which are invariably present in the air, and which prepare the way for more specifically putrefactive bacteria, such as *Proteus vulgaris* and *B. putrificus*, but it once observes a number of putrefactions of the same kind of matter under natural conditions, scarcely any two follow the same course. The modern study of putrefaction dates from Hauser, who, in 1885, isolated from putrefying flesh the three organisms—*Proteus vulgaris*, *P. mirabilis* and *P. zenkeri*. He studied the action of these in pure cultures, and came to the following conclusions:—

That *Bacterium termo* (Khr.) is not a single definite species; various forms and stages of other organisms have been described under this name. The various species of *Proteus* go through a wide range of forms during their development in which cocci, short and long rods, thread forms, vibrios, spirilli, and spirochaetae occur. Under special nutritive conditions *Proteus* goes through a swarm stage, in which condition it is capable of moving over the surface and in the solid gelatin. The *Proteus* bacteria are facultatively anaerobic, they all cause putrefaction; *P. vulgaris* and *P. mirabilis* are the commonest and most active of all putrefactive bacteria. They do not secrete an unorganised ferment, but decompose albuminous bodies by direct action. They also produce a powerful poison, of which small quantities injected into animals produce septicaemia.

Tito Carbone (3) found amongst the products of *P. vulgaris*, choline, ethylenediamine, gadimine, and trimethylamine. Macé, criticising Hauser's work, considers the cocci form of *Proteus* to be spores. Biensack (5) believes the rôle of the *Proteus* group somewhat doubtful. He discovered (1884) another widely distributed putrefactive organism, which he called *Bacillus putrificus*; it is a spore bearing, drumstick shaped bacillus found in faeces; it is anaerobic and specially attacks fibrin. Now fibrin is extremely resistant to the action of most putrefactive bacteria, and it is very probable that specific organisms ferment the different albuminous compounds in the same way that the different carbohydrates are each decomposed by specific ferments. A certain number of species of bacteria are able to decompose both carbohydrates and proteins. Tissier and Martelly (13) call these mixed ferments, and divide them further into two groups (1), mixed proteolytic ferments, including *B. perfringens*, *B. bifermensans sporogenes*, *Staphylococcus albus*, *Micrococcus flavus liquefaciens*, *Proteus vulgaris*, this

group decompose albumin by means of tryptic enzymes. (2) Mixed peptolytic ferments are only able to attack the albumin when it has undergone a preliminary decomposition. This group comprises *B. coli*, *B. filiformis*, *Streptococcus pyogenes*, *Diplococcus griseus non liquefaciens*.

The second class of bacteria are those which are without action on carbohydrates, and only attack proteids; these consist of the true proteolytic bacteria *B. putrificus*, and *B. putridus gracilis*, and the peptolytic bacteria, *Diplococcus magnus anaerobius* and *Proteus zenkeri*, which can only decompose peptones.

These authors state that *B. putrificus* is always present in putrefying albumin, but always accompanied by facultative aerobes which favour the growth and development of the special putrefactive bacteria.

In the putrefaction of meat the reaction is first acid owing to the action of the mixed ferments on the sugars present. In the next stage ammonia is formed by the tryptic enzymes secreted by the aerobic bacteria, and so the anaerobic organisms are enabled to develop. We can thus understand how it is that putrefaction proceeds more rapidly the more mixed ferments there are present, although these were formerly supposed to hinder putrefaction from taking place.

When meat is exposed to air it is first attacked by the mixed ferments. *Micrococcus flavus liquefaciens*, *Staphylococcus*, *Bacillus coli*, *Bacillus filiformis*, *Streptococcus* and *Diplococcus*, and becomes acid, at the same time the presence of decomposition products of albumin may be detected, proteoses, amidoacids, amines and ammonia; the latter quickly neutralise the acids, and in three to four days the meat is alkaline, and has a faint putrid smell. *Bacillus perfringens* and *Bacillus bifermensans sporogenes* now make their appearance; the latter of these organisms produces amines, amido-acids and ammonia. In this stage the simple anaerobic ferments are able to begin their work, and real putrefaction sets in; as this proceeds, the mixed ferments gradually disappear and finally the only organisms remaining are *Bacillus putrificus*, *Bacillus gracilis putridus*, and *Diplococcus griseus nonliquefaciens*.

Another organism, which appears to play an important part in the decomposition of animal bodies, is described by Klein (6); he found that in bodies, which had been buried from three to six weeks, bacteria such as *B. coli* and *B. proteus* had almost disappeared, and an anaerobic bacterium, which he calls *B. cadaveris sporogenes*, was very active. It is a motile bacillus 2–4 μ long, with flagella all over its surface. Spores are formed at the rounded ends, giving it a drumstick form. It coagulates milk, the clot gradually dissolving. It grows on all the usual nutritive media, but only under strictly anaerobic conditions.

In a paper, entitled "Fermentation in the Leather Industry" (this J., 1894, 218), I gave a short account of the progress of putrefaction as it takes place in the animal skin, and also described some of the organisms I had observed in putrefying skin. A small piece of skin was placed in water and allowed to stand at room temperature. During the first two days there was little change, but on the third day a number of swiftly moving darting monads made their appearance. Some of these were propelled by flagella, but a few had assumed amoeboid forms. A slowly moving bacillus consisting of a long straight rod, apparently broken up into cells exactly like the *Vibrio subtilis*, illustrated in the "Micrographic Dictionary," was observed, accompanied by some species of spirillum. Higher organisms present were a *Paramoecium* and a colourless transparent piece of protoplasm, shaped like a dumb-bell, with a slow rotating motion. On the fifth day the number of vibrios and spirilli had greatly increased, some with a swifter motion than others. There were also many large infusoria present; one of a peculiar double form which appeared to be a development of the dumb-bell shaped piece of protoplasm seen on the third day. On the seventh day the most striking feature was the great increase in the number of vibrios; the field of the microscope was crowded; masses of the bacilli could be seen clustered round small particles of the disintegrating skin as if feeding upon it; there were more infusoria, many of them short, boat-shaped monads, with a trembling motion, refracting light strongly; these evidently accom-

pany the putrefaction bacteria, and assist in the final disintegration. On the ninth day the piece of skin was entirely dissolved.

Proctor calls attention to the relative putrescibility of the different constituents of skin, and especially to the rapid putrescence of the lymph and serum. So far as I know, this part of the subject has not been studied at all thoroughly, and there is a considerable field open to workers in our research laboratories.

Pure fat is not decomposed by bacteria, but if albuminous matter is present, the fat is split up by several species of bacteria and moulds. Schreiber (18) has shown that the presence of oxygen is necessary. As this subject scarcely comes within the category of putrefaction, I refer you to Schreiber's paper, and also to an important paper by Otto Rahn (17) recently published.

In the putrefaction of vegetable matter the cellulose is attacked by specific organisms, which have been thoroughly investigated by Omeliansky (18). He has shown that the fermentation of cellulose is an anaerobic process, caused by two species of bacteria belonging to the class of butyric ferments. Morphologically the organisms closely resemble one another, but one of them decomposes the cellulose with evolution of hydrogen, the other with evolution of methane; in both cases considerable amounts of acetic acid and normal butyric acid are produced.

The rottenness of fruit is caused mainly by different species of moulds, and has recently received considerable attention on the Continent and in America. One of the principal organisms concerned is a species of *Fusarium*, isolated and described by Osterwalder (15) under the name of *Fusarium putrefaciens*. I give a list of the principal moulds known to take part in putrefaction.

I have previously stated that monads and infusoria take part in the process of putrefaction, but I do not know that their action has been studied in the same way as that of bacteria. The life history and morphology of some of these monads was studied in 1871 to 1875 by Dallinger and Frysdale (19). These authors in their researches into the life history of the monads found in a putrefying infusion of cod's head, came to the conclusion that "bacteria are not the only or even (in the end) the chief organic agents of putrefaction, for most certainly in the later stages of a disintegration of dead organic matter the most active agents are a large variety of flagellate monads."

Dallinger cultivated some of the monads in Cohn's fluid and found that they lived and multiplied in it. Their spores were killed at a temperature of 250° F. There is a big field of research open in this direction.

The consideration of the chemical aspect of putrefaction is a vast subject and would demand a special treatise. I shall only call your attention to one or two points of interest.

Taking the simpler bodies first, sulphuretted hydrogen is formed in putrefying liquids in two ways—1. By reduction of the sulphates in the liquid by an anaerobic organism *Spirillum desulfuricans*; 2. By bacteria capable of growing in the presence of oxygen such as *B. coli commune* and *B. lactis aerogenes*, which ferment glucoses with formation of levorotatory lactic acid and evolution of CO₂ and hydrogen, and if at the same time the material contains albumen or sulphur, H₂S is given off; these organisms are incapable of reducing sulphates. Boyerinek (7) has investigated this process, and found a variety of different forms intermediate between the two above-mentioned, but all possessing the same characteristics so far as their chemical action is concerned, so that they may be classed as one order which he calls *Aerobacter*.

Stich (8) found phosphorus pentoxide in the residue from the putrefaction of casein, nuclein, lecithin and protagon, and in the putrefaction of certain organs of animals and plants gases containing phosphorus are evolved. The nucleic acid of yeast yielded phosphoric acid along with hypoxanthin and xanthin.

Vitali (9) found in the putrefaction of muscle, which had been freed from sugars and fat, that some alcohol was produced. He considers that a hexose is split off from the albumin in a similar manner to the splitting off of a fermentable sugar from the glucoproteids (compounds of simple proteins with carbohydrates). The formation of

alcohol in the putrefaction of muscle occurs in the alkaline stage. Thus alcoholic fermentation is caused not alone by *saccharomyces*, but also by certain putrefactive bacteria.

Lerner (20) finds that the putrefaction of barley resembles butyric fermentation. An analysis of the gases given off during the later stages of the process gave the following result:—Nitrogen, 58.88; Hydrogen, 37.43; Methane, 3.15.

In the residue from the putrefaction he found acetic, butyric and valeric acids, but not caproic or caprylic acid. In the normal steeping process employed for barley the gases given off consisted almost entirely of carbon dioxide and nitrogen. This observation is interesting to compare with the evolution of nitrogen in the fermentation of bran shown by Wood and Wilcox (this J., 1893, 422).

The action of putrefactive bacteria has been found capable of transforming hexoses into pentoses. Salkowski and Nenberg (21) inoculated a solution of *D*-glukuronio acid with putrefying meat, and showed that it was changed into *L*-xylose with evolution of CO₂ according to the following formula:

This is an interesting fact, especially as, according to Nenberg, the pectose contained in animal nucleoproteids is *L*-xylose.

In conclusion, I hope that this short review of the subject will be of use in bringing together a good many references to work scattered in various periodicals. I also wish to express my indebtedness to Dr. Alfred Koch's "Jahresbericht über Gärungs-organismen" for some of the abstracts.

List of putrefactive bacteria which have been studied in pure cultures:—

1. *Proteus Vulgaris* (Hauser). 2. *Proteus mirabilis*. 3. *Proteus Zenckeri*. 4. *Bacillus Oedematis maligni* (Kerry, Nencki, Boveri). 5. *Bacillus Chauvvei* = *B. sarcophymatos bovis*. 6. *B. Liquefaciens magnus*. 7. *B. spinosus*. 8. *B. putrificus* (Bientock). 9. *B. pseudo oedematis* (Liborius). 10. *B. enteridis sporogenes* (Klein). 11. *B. tetani*. 12. *Clostridium fœtidum*. 13. *B. oedaveris sporogenes* (Klein). 14. *Spirillum desulfuricans*.

of it may be divided into two parts—(1) the biological, (2) the chemical. The first concerns the organisms which break down the proteid molecule either directly or by means of enzymes; the second that of the different products of the action of these organisms. It is extremely difficult to separate these two studies.

Dr. Sims Woodhead (2) gives a concise account of the earliest researches on the organisms causing putrefaction by Leewenhoeck (1692), Pleniz of Vienna, Müller of Copenhagen (1786), Needham (1749), Spallanzani (1769), Schwann (1837), Schroeder and Van Dusch (1854), Tyndall (1870), Lister (1878). These names show that the history of putrefaction proceeds parallel with the evolution of the microscope and the development of the comparatively recent science of bacteriology. I propose to-night briefly to carry it up to the present day.

I need scarcely say that putrefaction is not a specific fermentation like alcoholic or acetic fermentation, but that it is extremely complex. In any putrefying matter, such as gelatin or albumin, a large number of different species of bacteria may be observed as well as monads and infusoria, and in some cases moulds, all of which take part in the process. The first stage is a process of oxidation in the presence of air, in which aerobic bacteria use up the oxygen present and only simple inorganic compounds are formed, carbon dioxide, nitrates and sulphates; this part of the process is generally without odour. The second stage, or true putrefaction, takes place in the absence of oxygen by anaerobic bacteria, and is a process of reduction. It has been shown that there are no bacteria in healthy tissues, and if a muscle or any organ is taken from an animal under antiseptic conditions it may be preserved indefinitely in a sterile vessel to which filtered air has free access. Solid matter is usually liquefied by organisms like *B. liquefaciens* magnus, which are invariably present in the air, and which prepare the way for more specifically putrefactive bacteria, such as *Proteus vulgaris* and *B. putrificus*, but it once observes a number of putrefactions of the same kind of matter under natural conditions, scarcely any two follow the same course. The modern study of putrefaction dates from Hauser, who, in 1885, isolated from putrefying flesh the three organisms—*Proteus vulgaris*, *P. mirabilis* and *P. zenkeri*. He studied the action of these in pure cultures, and came to the following conclusions:—

That *Bacterium termo* (Khr.) is not a single definite species; various forms and stages of other organisms have been described under this name. The various species of *Proteus* go through a wide range of forms during their development in which cocci, short and long rods, thread forms, vibrios, spirilli, and spirochaetae occur. Under special nutritive conditions *Proteus* goes through a swarm stage, in which condition it is capable of moving over the surface and in the solid gelatin. The *Proteus* bacteria are facultatively anaerobic, they all cause putrefaction; *P. vulgaris* and *P. mirabilis* are the commonest and most active of all putrefactive bacteria. They do not secrete an unorganised ferment, but decompose albuminous bodies by direct action. They also produce a powerful poison, of which small quantities injected into animals produce septicaemia.

Tito Carbone (3) found amongst the products of *P. vulgaris*, choline, ethylenediamine, gadimine, and trimethylamine. Macé, criticising Hauser's work, considers the cocci form of *Proteus* to be spores. Biensack (5) believes the rôle of the *Proteus* group somewhat doubtful. He discovered (1884) another widely distributed putrefactive organism, which he called *Bacillus putrificus*; it is a spore bearing, drumstick shaped bacillus found in faeces; it is anaerobic and specially attacks fibrin. Now fibrin is extremely resistant to the action of most putrefactive bacteria, and it is very probable that specific organisms ferment the different albuminous compounds in the same way that the different carbohydrates are each decomposed by specific ferments. A certain number of species of bacteria are able to decompose both carbohydrates and proteids. Tissier and Martelly (13) call these mixed ferments, and divide them further into two groups (1), mixed proteolytic ferments, including *B. perfringens*, *B. bifermens* sporogenes, *Staphylococcus albus*, *Micrococcus flavus liquefaciens*, *Proteus vulgaris*, this

group decompose albumin by means of tryptic enzymes. (2) Mixed peptolytic ferments are only able to attack the albumin when it has undergone a preliminary decomposition. This group comprises *B. coli*, *B. filiformis*, *Streptococcus pyogenes*, *Diplococcus griseus* non liquefaciens.

The second class of bacteria are those which are without action on carbohydrates, and only attack proteids; these consist of the true proteolytic bacteria *B. putrificus*, and *B. putridus gracilis*, and the peptolytic bacteria, *Diplococcus magnus anaerobius* and *Proteus zenkeri*, which can only decompose peptones.

These authors state that *B. putrificus* is always present in putrefying albumin, but always accompanied by facultative aerobes which favour the growth and development of the special putrefactive bacteria.

In the putrefaction of meat the reaction is first acid owing to the action of the mixed ferments on the sugars present. In the next stage ammonia is formed by the tryptic enzymes secreted by the aerobic bacteria, and so the anaerobic organisms are enabled to develop. We can thus understand how it is that putrefaction proceeds more rapidly the more mixed ferments there are present, although these were formerly supposed to hinder putrefaction from taking place.

When meat is exposed to air it is first attacked by the mixed ferments. *Micrococcus flavus liquefaciens*, *Staphylococcus*, *Bacillus coli*, *Bacillus filiformis*, *Streptococcus* and *Diplococcus*, and becomes acid, at the same time the presence of decomposition products of albumin may be detected, proteoses, amidoacids, amines and ammonia; the latter quickly neutralise the acids, and in three to four days the meat is alkaline, and has a faint putrid smell. *Bacillus perfringens* and *Bacillus bifermens* sporogenes now make their appearance; the latter of these organisms produces amines, amidoacids and ammonia. In this stage the simple anaerobic ferments are able to begin their work, and real putrefaction sets in; as this proceeds, the mixed ferments gradually disappear and finally the only organisms remaining are *Bacillus putrificus*, *Bacillus gracilis putridus*, and *Diplococcus griseus nonliquefaciens*.

Another organism, which appears to play an important part in the decomposition of animal bodies, is described by Klein (6); he found that in bodies, which had been buried from three to six weeks, bacteria such as *B. coli* and *B. proteus* had almost disappeared, and an anaerobic bacterium, which he calls *B. cadaveris sporogenes*, was very active. It is a motile bacillus 2–4 μ long, with flagella all over its surface. Spores are formed at the rounded ends, giving it a drumstick form. It coagulates milk, the clot gradually dissolving. It grows on all the usual nutritive media, but only under strictly anaerobic conditions.

In a paper, entitled "Fermentation in the Leather Industry" (this J., 1894, 218), I gave a short account of the progress of putrefaction as it takes place in the animal skin, and also described some of the organisms I had observed in putrefying skin. A small piece of skin was placed in water and allowed to stand at room temperature. During the first two days there was little change, but on the third day a number of swiftly moving darting monads made their appearance. Some of these were propelled by flagella, but a few had assumed amoeboid forms. A slowly moving bacillus consisting of a long straight rod, apparently broken up into cells exactly like the *Vibrio subtilis*, illustrated in the "Micrographic Dictionary," was observed, accompanied by some species of spirillum. Higher organisms present were a *Paramoecium* and a colourless transparent piece of protoplasm, shaped like a dumb-bell, with a slow rotating motion. On the fifth day the number of vibrios and spirilli had greatly increased, some with a swifter motion than others. There were also many large infusoria present; one of a peculiar double form which appeared to be a development of the dumb-bell shaped piece of protoplasm seen on the third day. On the seventh day the most striking feature was the great increase in the number of vibrios; the field of the microscope was crowded; masses of the bacilli could be seen clustered round small particles of the disintegrating skin as if feeding upon it; there were more infusoria, many of them short, boat-shaped monads, with a trembling motion, refracting light strongly; these evidently accom-

Filtering, Purifying, and Decanting Apparatus. H. Desmaux, Paris. U.S. Pat. 809,096, Jan. 2, 1906.

A NUMBER of superposed filtering chambers communicate with one another by central overflow pipes, which extend from above the level of the filtering medium in one chamber through the partition which divides it from the one below. The filtering medium is supported on perforated plates, and each chamber is provided with revolving stirring bars, having "fingers" or projections depending from them and adapted to stir up the filtering medium. Valved outlet pipes are connected to each chamber above and below the level of the filtering medium.—W. H. C.

FRENCH PATENTS.

Drying-Stove. A. Schroder. Fr. Pat. 357,768, Aug. 28, 1905. Under Int. Conv., Aug. 30, 1904.

A DRYING chamber enclosed on three sides by hollow walls, and on the fourth by a double-walled door, is heated by hot air circulating through the hollow walls which are provided with regulating dampers. The air itself is heated by being passed through a chamber, fitted with baffles and filled with metal turnings or shavings to assist in the absorption of heat by the air. The chamber is placed beneath the drier and heated by external gas jets which are arranged in double rows beneath the corrugated bottom of the air-heating chamber. The corrugations serve the double purpose of providing a large heating surface and forming channels for the escape of the products of combustion. The materials to be dried are placed on trays which are supported on ledges or grooves on the two side walls of the drying chamber, a space being left between the ends of the trays and the back wall for the escape of the vapours given off.—W. H. C.

Drying by Exposure to Light; Method of —. Ges. für Trockenverfahren, m.b.H. Fr. Pat. 357,895, Sept. 23, 1905. Under Int. Conv., Sept. 22, 1904.

SEE Ger. Pat. 102,696 of 1904; this J., 1906, 59.—W. H. C.

Concentration of Solutions by the method of freezing and the removal of the Ice Crystals from the soluble Matter; Process and Apparatus for —. E. Mouti. Fr. Pat. 357,770, Sept. 7, 1905.

THE present patent relates to improvements in Fr. Pat. 324,472 of 1902 (this J., 1903, 567), and claims are made for the progressive freezing of the solutions from above downwards; the utilisation of the heat rendered latent during the fusion of the ice crystals to cool the refrigerating gas; the use of a gas to saturate and agitate the solutions being frozen, which gas may or may not act chemically on the solution; and the application of the process to the concentration of solutions of alcohol, sugar, salts, acids, &c.—W. H. C.

Mixing two or more Liquids in a determined proportion; Apparatus for —. W. J. Schumacher. Fr. Pat. 357,863, Sept. 19, 1905.

THE bucket-wheel *z z* (Fig. 1) is mounted on a shaft carried by supports *l l'* (Fig. 2) and is fed with liquid through the pipe *r¹* (Fig. 1). The wheel is prevented from rotating, while it is being filled, by the weighted lever stop *u¹, u², g¹*, the balance of which is so adjusted that the projection *p* cannot clear the bent end until the liquid in *z* is sufficient to overcome the resistance of the weighted lever. Consequently, by varying the weight on the lever, the rate at which the wheel buckets fill can be varied. The projections *p p¹* serve the further purpose of retarding the movements of the wheel when it is turning, owing to the resistance offered to their movement by the air or liquid. As the wheel turns round, the contents of each bucket in succession are emptied into the tank *b₁* and flow from thence to the mixing tank proper by the pipe *r₂*; at the same time the dipper *sch* carried on the hollow arm *r₃* is made to take up a quantity of liquid from the tank *b₂*, and as the wheel rotates, to empty it into the mixing tank through the shoot *a* and *r₅* (Fig. 2). As many arms *r₃* and scoops *sch* may be used as there are liquids to be

mixed; the liquids are stored in separate tanks, each of which has its own scoop. The apparatus described is claimed for the mixing of two or more liquids together in determined proportion.—W. H. C.

Reagents; Process and Apparatus for Preparing and Feeding —. J. F. Wixford. Fr. Pat. 357,941, Sept. 22, 1905. Under Int. Conv., Sept. 22, 1904.

SEE U.S. Pat. 804,945 of 1905; this J., 1906, 72.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

(Continued from page 62.)

Oil-Burning equipment; A simple — C. De Kalb.
Eng. and Mining J., 1906, 81, 74.
ONE of the most important points in connection with

the use of liquid fuel, is the delivery of the oil to the burner under constant pressure. The author points out that uniform pressure can be most easily maintained when the oil rises in the suction-pipe of the pump with a low velocity, and this can only be attained by using a pump of large capacity. The plant shown in the accompanying figure has proved satisfactory in practice. The oil is drawn from the supply-tank through the suction pipe OS (2 in. diam.) and delivered through pipe OD (1½ in. diam.) to the reservoir H (6 in. diam.), where it is preheated to a certain extent by the exhaust steam from the pump passing through the pipe SE (1½ in. diam.). From the reservoir H, rises a stand-pipe K (6 in. diam.) provided with a weighted valve W, which opens when the pressure exceeds a determined limit; any oil which overflows is returned to the supply-tank through the pipe Q. Any gas accumulating in the pump is blown off through the pipe G D. From the reservoir H, the oil is supplied through pipe O¹ D¹ to the burner, which consists of an oil-tube of ¾ in. diam. disposed concentrically within a 1 in. steam-pipe, terminating a few inches beyond the oil tube. The end of the steam-pipe is in the form of a flattened lip with a slit in the shape of an arc of a circle so disposed that it would be bisected by the (prolonged) longitudinal axis of the oil-tube.—A. S.

Calcium Hydride; Occurrence of a Gaseous — in commercial Acetylene. C. Hoffmeister. Z. anorg. Chem., 1906, 48, 137—139.

THE author has frequently observed, on the cooler parts of an acetylene gas plant, white deposits consisting of lime or, when the deposit had been exposed to the air for some time, calcium carbonate. This deposit has been traced to the presence in the acetylene of a gaseous compound of calcium and hydrogen. The compound was separated by passing some of the acetylene containing it successively through a filter of cotton-wool, a number of flasks containing acetone, and finally through ammoniacal copper solution. From 100—150 c.c. were obtained from 100 litres of acetylene, but the gas still contained admixed air. It is colourless, has an odour resembling that of commercial acetylene and hydrogen phosphide, and is very slightly soluble in water. It burns with an intense calcium flame, and, when mixed with oxygen, gives an extremely explosive mixture; the only products of combustion detected were lime and water.—A. S.

Calcium Carbide and Acetylene. J. H. Vogel, Z. angew. Chem., 1906, 19, 49—57.

THE German production of carbide in 1905 was about 8000 tons, and the import about 16,000 tons. From 1 kilo. of

carbide are obtained, in practice, about 290 litres of acetylene (97 per cent. of the theoretical yield), so that 24,000 tons of carbide replace for lighting purposes about 13 million galls. of petroloum. While five years ago the price of carbide was 50—60 marks per 100 kilos., at present it is produced at 22 marks per 100 kilos.—J. T. D.

ENGLISH PATENTS.

Burners; Liquid Fuel — C. Leistner, London.
Eng. Pat. 24,372, Nov. 10, 1904.

THE burner consists of an outer conical casing, an inner concentric casing divided by a partition into oil and compressed-air chambers, nozzles secured to these chambers to form annular outlet passages for the oil and air respectively, and a central spindle acting as an oil regulating valve. Compressed air is admitted to both the outer and inner casings, the arrangement being such that the mixture of atomised fuel and air, issuing from the nozzle of the inner casing, is completely surrounded by an annular jacket of air. For the automatic regulation of the oil supply, according to variations in the air pressure, a branch tube from the air pipe is connected to a cylinder containing a spring-controlled piston, which is linked to the cock of the oil supply pipe.—H. B.

Burners; Gaseous Fuel — F. A. Wegner, Brookville, Ontario, Canada. Eng. Pat. 137, Jan. 3, 1905.

THE end of the gas-supply pipe is screwed into a concentric mixing pipe, which leads to the burners and is provided with a lateral branch pipe through which air is introduced from a blower or other air-forcing device. The gas supply pipe projects into the mixing pipe for a short distance beyond the point at which the air enters.—H. B.

[Suction] *Gas Producers.* L. W. Crosta and G. L. Morton, Nottingham. Eng. Pat. 6434, March 27, 1905.

THE gas outlet pipe, between the producer and the scrubber, is provided with corrugations, ribs, or the like, to present an extended heating surface, and is surrounded by the air inlet pipe, so that the air becomes heated in flowing through the annular space between the two pipes. The air then enters an annular mixing chamber for air and steam, which surrounds the upper part of the producer, and is there mixed with steam which is generated continuously in an annular boiler surrounding the incandescent zone of the fuel. The annular steam-pipe, which admits the steam to the mixing chamber, also communicates with a bell, immersed in water, outside the producer, this device serving to condense the steam when the gas production ceases, thus preventing the accumulation of steam in the mixing chamber. The tuyères, through which the air and steam from the mixing chamber are admitted into the lower part of the furnace, are fitted with wire gauze, small tubes, or other devices, which deliver the mixture to the furnace in fine streams.—H. B.

Gas; Apparatus for the manufacture of — H. P. Bell. London. Eng. Pat. 6794, March 31, 1905.

THE apparatus consists of three vessels provided with jackets, the vessels and the jackets being connected by pipes, controlled by valves, so that each vessel in turn becomes the first, second, and third of the series. The apparatus is worked in a cycle of three stages, the gases, or part of them from the first vessel at each stage being discharged into the air after passing through the jackets surrounding the other two vessels, and the gases generated in the second vessel at each stage passing through the third vessel before leaving the apparatus. The apparatus is for the production of water-gas or producer gas from suitable fuel, air being admitted to the first vessel and steam to the second vessel, with or without air or part of the gases from the first vessel, and fuel being introduced into the second vessel at each stage.—W. C. H.

Generator or Water-Gas; Production of Carburetted — J. A. Hutmaacher, Berlin. Eng. Pat. 19,996, Oct. 3, 1905.

THE generator, which is fitted with feed-hopper, gas outlet

pipe, air-blast pipe, and steam supply pipe as usual, is also provided at one side of the combustion space, with a chamber, open at the lower end, which depends into the fuel as far as the incandescent zone. This chamber serves for vaporising and superheating the hydrocarbon used as the carburating material, which is admitted at the top through a siphon tube. The open end of the chamber is arranged at such a level that the hydrocarbon vapours are discharged into the incandescent fuel at a point above the oxidising zone. Combustion of the vapours is thus prevented, but the temperature is nevertheless sufficiently high to convert the vapours into permanent gases.—H. B.

Gases; purification of, and recovery of Tar and other Substances from Blast Furnace, Producer, and like — G. Neilson, Coathridge, N.B. Eng. Pat. 28,508, Dec. 28, 1904.

THE gas is led, on its way from the by-product plant to the gas-engine or the like, through a purifier consisting of a casing in which are fixed horizontal platforms or diaphragms, each carrying a number of tar-trapping vessels, whilst at the bottom of the casing the gas is admitted through an oil washer. Each tar-trap consists of a short vertical cylindrical tube, open at both ends, but provided at the top with a cover which is fixed so as to leave a narrow space—from one-fiftieth to one-sixteenth of an inch—between the cover and the upper edge of the cylinder. A conical rim or flange extends downwards from the cover a short distance round the cylinder, forming an annular space round the latter. The crude gas, passing up through the platform and the cylinder, issues in a thin sheet at high velocity through the narrow opening between the cylinder and cover, the tar, which is deposited on the conical flange, running down and being led off by a collecting pipe.—H. B.

Incandescent Lamps; Manufacture of light emitting Bodies for Electric — H. Kuzel, Baden, Austria. Eng. Pat. 28,154, Dec. 22, 1904.

IN manufacturing glow bodies from elements of high melting-point, such as chromium, manganese, molybdenum, uranium, tungsten, vanadium, tantalum, niobium, titanium, thorium, zirconium, platinum, osmium, iridium, horon, and silicon, a plastic mass composed of one or more of these in a colloidal state, without the addition of any binding material, is brought into the desired shape, dried slowly, and finally raised to a white heat in a neutral atmosphere. To obtain the plastic masses, the metals are obtained as colloidal suspensions, for example by Bredig's method, which consists in setting up a voltaic arc between two electrodes made of the metal, having a very rough surface and immersed in water. The colloidal suspension formed is then dried by slow evaporation to reduce it to a pasty condition.—H. B.

Incandescence Bodies for Electric Light; Manufacture of [Tantalum] — Siemens and Halske A. G., Berlin. Eng. Pat. 23,097, Nov. 10, 1905. Under Int. Conv., Nov. 15, 1904.

TANTALUM, which though of very high melting point can easily be drawn into fine wire, is used as a core upon which another difficultly fusible metal (such as osmium, tungsten or molybdenum) which cannot be fashioned easily into wires, is deposited. On raising the coated wire to a very high temperature, the tantalum and other metal form an alloy.—H. B.

Incandescence Bodies of Tungsten, Molybdenum or similar metals; Manufacture of [Electrical] Glow Lamps with — Siemens and Halske A. G., Berlin. Eng. Pat. 23,098, Nov. 10, 1905. Under Int. Conv., Nov. 15, 1904.

IN manufacturing glow-lamps with filaments of difficultly-worked metals, such as tungsten and molybdenum, a fine metal wire or carbon filament, serving as core in the first instance, is stretched between a series of supporting devices upon a frame adapted to be introduced into the lamp globe (see Eng. Pat. 27,712 of 1903). The incandescence metal is then deposited upon the stretched wire, for example by heating it in an atmosphere of hydrogen

and tungsten oxychloride. Tantalum wire is particularly suitable for use as the core of the filament. (See Eng. Pat. 28,508 in preceding Eng. Pats.)—H. R.

Gas-Producers; Process of preventing the formation of Clinker in — J. E. Sheaffer, Assignor to O. C. Skinner, Burnham, Pa. U.S. Pat. 809,021, Jan. 2, 1906.

THE claim is for the process of preventing the formation of clinker in gas-producers, by agitating the fuel and injecting water through the hollow arms of the agitator into the mass of incandescent fuel at points near the walls of the generator, where the clinker most commonly forms.—W. H. C.

Gas-Producer. O. C. Skinner and J. E. Sheaffer, Burnham, Pa. U.S. Pat. 809,023, Jan. 2, 1906.

A HOLLOW, water-cooled shaft with hollow, water-cooled agitating arms is arranged to be rotated within a producer. The arms are rotated within the mass of fuel, and have nozzles through which a current of water is discharged towards the sides of the producer.—W. H. C.

Gases; Apparatus for the separation of — from their Mixtures. R. P. Pictet, Berlin. U.S. Pat. 809,218, Jan. 2, 1906.

SEE Eng. Pat. 19,254, of 1900; this J., 1901, 1194.—T. F. B.

Illuminant. J. Lewy, Frankfort-on-Maine, Germany. U.S. Pat. 809,121, Jan. 2, 1906.

FRENCH PATENTS.

Anthracite Dust; Process for the Agglomeration of — A. Exbrayat. First Addition, dated March 11, 1905 to Fr. Pat. 350,258, Oct. 25, 1904. (This J., 1906, 10.)

INSTEAD of resin, quicklime or calcium salts may be added to the gelatinous mass prepared from seaweed (fucus) in order to dehydrate it. The briquettes are hardened by the addition of formaldehyde or alkali peroxides, previously mixed with alkali silicates.—W. H. C.

Combustible [Briquette]; Manufacture of Agglomerated — A. Benaïmé and A. Requier. Fr. Pat. 357,631, Sept. 9, 1905.

A MIXTURE of anthracite, coke, or non-coking coal dust, with tar, pitch, coking-coal or other agglomerant, is first briquetted and then heated in a retort or oven to such a temperature that the volatile products are distilled off. The briquettes may be further hardened by immersing them, while still hot, in a solution of an alkali silicate, or the silicate may be added before the heating takes place. The use of briquettes, so prepared, which are said to produce neither smoke nor smell on burning, for domestic fires, especially in slow-combustion stoves, and for industrial furnaces is claimed. Further, if the briquettes are intended for use in metallurgical operations in which the evolution of sulphur dioxide from the contained sulphur is objectionable, the latter is fixed by the previous addition of a suitable proportion of lime, magnesia or other metallic oxide.—W. H. C.

Briquettes of any Materials; Process for the manufacture of hard and compact — L. Weiss. Fr. Pat. 357,801, Sept. 16, 1905.

COMBUSTIBLE substances, ores or other materials are formed into compact briquettes by mixing them with milk of lime, compressing in moulds, and subjecting the mass either during or after compression to the action of carbon dioxide at a pressure of from 8 to 25 atmospheres. The carbon dioxide may be introduced into the closed moulds or into reservoirs preferably constructed of "Mannesmann" tubes, containing the compressed briquettes.—A. S.

Furnace; Retort — Soc. P. de Lachomette, Villiers and Cie. Fr. Pat. 357,804, Sept. 16, 1905.

To prevent, in the distillation of coal, the upper portions

II.—FUEL, GAS, AND LIGHT.

(Continued from page 62.)

Oil-Burning equipment; A simple — C. De Kalb.
Eng. and Mining J., 1906, 81, 74.
ONE of the most important points in connection with

the use of liquid fuel, is the delivery of the oil to the burner under constant pressure. The author points out the uniform pressure can be most easily maintained when the oil rises in the suction-pipe of the pump with a low velocity, and this can only be attained by using a pump of large capacity. The plant shown in the accompanying figure has proved satisfactory in practice. The oil is drawn from the supply-tank through the suction pipe OS (2 in. diam.) and delivered through pipe OD (1½ in. diam.) to the reservoir H (6 in. diam.), where it is preheated to a certain extent by the exhaust steam from the pump passing through the pipe SE (1½ in. diam.). From the reservoir H, rises a stand-pipe K (6 in. diam.) provided with a weighted valve W, which opens when the pressure exceeds a determined limit; any oil which overflows is returned to the supply-tank through the pipe Q. Any gas accumulating in the pump is blown off through the pipe G D. From the reservoir H, the oil is supplied through pipe O¹ D¹ to the burner, which consists of an oil-tube of ¾ in. diam. disposed concentrically within a 1 in. steam-pipe, terminating a few inches beyond the oil tube. The end of the steam-pipe is in the form of a flattened lip with a slit in the shape of an arc of a circle so disposed that it would be bisected by the (prolonged) longitudinal axis of the oil-tube.—A. S.

Calcium Hydride; Occurrence of a Gaseous — in commercial Acetylene. C. Hoffmeister. Z. anorg. Chem., 1906, 48, 137—139.

THE author has frequently observed, on the cooler parts of an acetylene gas plant, white deposits consisting of lime or, when the deposit had been exposed to the air for some time, calcium carbonate. This deposit has been traced to the presence in the acetylene of a gaseous compound of calcium and hydrogen. The compound was separated by passing some of the acetylene containing it successively through a filter of cotton-wool, a number of flasks containing acetone, and finally through ammoniacal copper solution. From 100—150 c.c. were obtained from 100 litres of acetylene, but the gas still contained admixed air. It is colourless, has an odour resembling that of commercial acetylene and hydrogen phosphide, and is very slightly soluble in water. It burns with an intense calcium flame, and, when mixed with oxygen, gives an extremely explosive mixture; the only products of combustion detected were lime and water.—A. S.

Calcium Carbide and Acetylene. J. H. Vogel, Z. angew. Chem., 1906, 19, 49—57.

THE German production of carbide in 1905 was about 8000 tons, and the import about 16,000 tons. From 1 kilo. of

carbide are obtained, in practice, about 290 litres of acetylene (97 per cent. of the theoretical yield), so that 24,000 tons of carbide replace for lighting purposes about 13 million galls. of petroloum. While five years ago the price of carbide was 50—60 marks per 100 kilos., at present it is produced at 22 marks per 100 kilos.—J. T. D.

ENGLISH PATENTS.

Burners; Liquid Fuel — C. Leistner, London.
Eng. Pat. 24,372, Nov. 10, 1904.

THE burner consists of an outer conical casing, an inner concentric casing divided by a partition into oil and compressed-air chambers, nozzles secured to these chambers to form annular outlet passages for the oil and air respectively, and a central spindle acting as an oil regulating valve. Compressed air is admitted to both the outer and inner casings, the arrangement being such that the mixture of atomised fuel and air, issuing from the nozzle of the inner casing, is completely surrounded by an annular jacket of air. For the automatic regulation of the oil supply, according to variations in the air pressure, a branch tube from the air pipe is connected to a cylinder containing a spring-controlled piston, which is linked to the cock of the oil supply pipe.—H. B.

Burners; Gaseous Fuel — F. A. Wegner, Brookville, Ontario, Canada. Eng. Pat. 137, Jan. 3, 1905.

THE end of the gas-supply pipe is screwed into a concentric mixing pipe, which leads to the burners and is provided with a lateral branch pipe through which air is introduced from a blower or other air-forcing device. The gas supply pipe projects into the mixing pipe for a short distance beyond the point at which the air enters.—H. B.

[Suction] *Gas Producers.* L. W. Crosta and G. L. Morton, Nottingham. Eng. Pat. 6434, March 27, 1905.

THE gas outlet pipe, between the producer and the scrubber, is provided with corrugations, ribs, or the like, to present an extended heating surface, and is surrounded by the air inlet pipe, so that the air becomes heated in flowing through the annular space between the two pipes. The air then enters an annular mixing chamber for air and steam, which surrounds the upper part of the producer, and is there mixed with steam which is generated continuously in an annular boiler surrounding the incandescent zone of the fuel. The annular steam-pipe, which admits the steam to the mixing chamber, also communicates with a bell, immersed in water, outside the producer, this device serving to condense the steam when the gas production ceases, thus preventing the accumulation of steam in the mixing chamber. The tuyères, through which the air and steam from the mixing chamber are admitted into the lower part of the furnace, are fitted with wire gauze, small tubes, or other devices, which deliver the mixture to the furnace in fine streams.—H. B.

Gas; Apparatus for the manufacture of — H. P. Bell. London. Eng. Pat. 6794, March 31, 1905.

THE apparatus consists of three vessels provided with jackets, the vessels and the jackets being connected by pipes, controlled by valves, so that each vessel in turn becomes the first, second, and third of the series. The apparatus is worked in a cycle of three stages, the gases, or part of them from the first vessel at each stage being discharged into the air after passing through the jackets surrounding the other two vessels, and the gases generated in the second vessel at each stage passing through the third vessel before leaving the apparatus. The apparatus is for the production of water-gas or producer gas from suitable fuel, air being admitted to the first vessel and steam to the second vessel, with or without air or part of the gases from the first vessel, and fuel being introduced into the second vessel at each stage.—W. C. H.

Generator or Water-Gas; Production of Carburetted — J. A. Hutmaacher, Berlin. Eng. Pat. 19,996, Oct. 3, 1905.

THE generator, which is fitted with feed-hopper, gas outlet

must have, at a state of incandescence corresponding to 1.5 watts per candle, an electric resistance nine or more times greater than at ordinary temperature (20°C.). To obtain filaments answering these requirements, tungstic acid is heated in a hydrogen atmosphere at incipient red heat until its weight is constant, and is then made into a paste with a viscous solution of gum and caramel. The paste is formed into threads, and these are moderately heated first without access of air, then in an atmosphere of hydrogen, together with sufficient oxygen to eliminate the carbon. For the process of hardening, the temperature must be raised very high. To avoid deformation of the filaments, this must be done in an atmosphere of non-conducting gases or *in vacuo*.—R. L.

GERMAN PATENT.

Furnace for Drying and Carbonising Briquettes, working continuously and with exclusion of Air. Sächsishe Bankges. Quellmalz und Co. Gor. Pat. 163,033, June 29, 1904.

THE furnace comprises a number of chambers, open alternately above and below, through which the material (briquettes) is conveyed by means of an endless chain. The furnace casing is closed against the outer air, and only a few of the chambers or shafts in the middle of the furnace are directly heated, so that in passing through the apparatus, the material is heated very gradually until it reaches the middle, and is afterwards gradually cooled; by using a large number of chambers or shafts, the material may be sufficiently cooled when it reaches the exit, to be available directly for storage or transport.—A. S.

Pitch. U.S. Customs Decision, Nov. 29, 1905.

AN asphaltic bituminous compound, partly sulphonated and largely soluble in alkali, was held to be dutiable as "pitch," under the provision of paragraph 93 of the tariff, as claimed by the importer.—R. W. M.

UNITED STATES PATENTS.

Petroleum: Extracting Sulphur from the sulphur-containing constituents of —. H. S. Blackmore, Mount Vernon, N.Y. Assignor to Black-Ford Utility Oil Co., D.C. U.S. Pat. 809,086, Jan. 2, 1906.

THE sulphur-containing petroleum oils or petroleum constituents are exposed to the action of a metal (e.g., zinc-) hydrogen carbide, and the heat evolved during the reaction is absorbed by refrigeration, so that the sulphur is removed from the oil, and "hydrogen carbide" is formed.—C. S.

Petroleum: Eliminating Sulphur from the sulphur-containing constituents of —. H. S. Blackmore, Mount Vernon, N.Y. Assignor to Black-Ford Utility Oil Co., D.C. U.S. Pat. 809,087, Jan. 2, 1906.

THE petroleum oils, or petroleum constituents, containing sulphur are exposed to the action of a metal (e.g., nickel-) carbonyl. The process may be rendered continuous by converting the resulting metallic sulphide into oxide, deoxidising this oxide, and exposing it to the action of carbon monoxide "liberated during the precipitation of a previous increment of metal carbonyl," thus forming a fresh "increment" of metal carbonyl, which is employed for treating a fresh batch of oil.—C. S.

FRENCH PATENTS.

Benzene: Non-inflammable — and process of making same [by Chlorination]. E. B. Barboni. Fr. Pat. 350,313, Nov. 18, 1904.

THIRTY grms. of iodine are dissolved in a mixture of 100 kilos. of benzene and 12 litres of carbon bisulphide. A current of dry chlorine is then passed into the solution, which is kept well agitated in a vessel provided with a reflux condenser. The chlorination is said to be finished when iodine chloride is formed. At that stage, 1 kilo. of sulphur is added to the cooled solution, which is thoroughly agitated, and then distilled. The distillate is agitated with half its weight of water to decompose the sulphur chloride, and then with a 0.5 per cent. solution of sodium hydroxide, and is dried over calcium chloride and filtered. The resulting solution of chlorobenzenes in benzene is stated to be non-inflammable.—T. F. B.

Wood and Sawdust, Process for Treating — by distillation, to produce Wood Spirit, Acetic Acid, Acetone, and a substitute for Animal Charcoal. Onjavacer Chem. Fabrik, J., H., and A. Müller. Fr. Pat., 357,432, Sept. 2, 1905.

WOOD or sawdust is treated with a mineral acid, preferably sulphuric acid, and is then distilled, the vapours being passed through a red-hot iron tube. The following products are stated to be produced by treating 100 kilos. of wood (containing 35 per cent. of moisture) with 20 kilos. of sulphuric acid, and then distilling up to 160° C., and rectifying the distillate:—3 kilos. of wood alcohol, 7 kilos. of acetic acid, 2 kilos. of oil of turpentine, and 40 kilos. of a wood charcoal of high specific gravity, which may be used in place of animal charcoal.—T. F. B.

(Continued from page 71.)

Cotton and Worsted; Comparative data on Moisture in —. W. D. Hartshorne. Paper read before New England Cotton Manufacturers' Assoc., Sept. 21, 1905.

THE paper relates to the average natural condition of worsted yarn and cotton, as determined by the percentage absorption of moisture by the dry yarn, in the neighbourhood of Lawrence, Mass., U.S.A. Results of experiments, extending over a period of a year, on a skein of worsted yarn, the absolutely dry weight of which was known, are given. Variations of from 7 to 35 per cent. on the dry weight were observed, and even 19 per cent. during 24 hours, the weight being generally greater in the morning than in the afternoon. The average for the year was 17.45 per cent. of moisture absorbed. Experiments, to trace the relationship between atmospheric humidity and temperature and the absorbing capacity of fibres, have been made, and, for the determination of the former in factories, the author recommends a new form of wet and dry bulb apparatus called the sling hygrometer or psychrometer. The operator slings or whirles the apparatus as he walks through a room, and rapid observations of differences in conditions may be obtained. For a given humidity and temperature, a higher result is obtained with a falling percentage of moisture in the yarn and the opposite effect with a rising, but by experiments made with two similar skeins, exposed previously to a damp and to a dry atmosphere, it has been shown that after 20 minutes the mean between the two weights gives the true relationship. A new method of charting the results is shown, using the percentages of absorption and the grains of aqueous vapour per cubic foot as co-ordinates. From the results the isothermal curves, 5° F. of temperature apart, from 35° to 100° F., and the curves of relative humidity from 15 per cent. to saturation for worsted and cotton, have been plotted. Similarly, by using temperature and grains of aqueous vapour per cubic foot as co-ordinates, curves have been plotted, showing that, at ordinary mill temperatures, the $7\frac{1}{2}$ per cent. cotton curve agrees closely with the 15 per cent. absorption worsted curve, and these cross a 60 per cent. humidity curve at 77° F., a room condition which has been stated to be compatible with good work and comfort in cotton spinning. In an appendix, tables and an analysis of the year's observa-

tions are given, together with some mathematical deductions establishing the general physical law of absorption of moisture by textile fibres, especially worsted.—B. N.

Textile Fibres; Behaviour of Animal and Vegetable — towards solutions of Metallic Salts. W. Schellens. Arch. Pharm., 1905, 243, 617—631.

WHEN animal or vegetable textile fibres are macerated in aqueous solutions of metallic salts, at this normal temperature, a portion of the base is fixed in such a manner that it cannot be removed except by chemical reagents. In order to determine the fixing power of various fibres, 1 grm. of each was macerated in 50 c.c. of solutions of various salts, in a closed vessel, for several days. The fibre was then washed and boiled with water until no reaction for either the acid or the base was obtained with the washings.

Fixing of Iron.—With an aqueous solution of ferrous chloride containing 1 per cent. of iron, filter-paper fixed 0.229 per cent. of iron; pure cotton-wool, 0.112 per cent.; kapok fibre, 1.008 per cent.; Indian jute, 0.56 and 0.44 per cent.; raw silk and Japanese silk, 0.672 per cent.; wool, previously freed from fat with light petroleum spirit, 0.84 per cent. Similar experiments with 0.1 per cent. solutions gave corresponding, but lower, results. With alcoholic solution of ferric chloride, cotton-wool fixed 0.22 per cent. of iron both from 1.0 and 0.1 per cent. solutions; paper, 0.56 per cent.; kapok, 1.56 per cent.; jute, 0.78 per cent.; silk, 1.23 per cent.; wool, 2.27 per cent., and practically half as much from 0.1 per cent. solutions. With an aqueous solution of ferric acetate containing 1 per cent. of iron, cotton-wool fixed 0.39 per cent. of iron; paper, 0.41 per cent.; kapok, 0.78; jute, 0.78 per cent.; silk, 1.26 per cent.; wool, 0.448 per cent. Pure cellulose was found to behave similarly to cotton-wool.

Fixing and Absorption of Mercury.—With solutions of mercuric chloride containing 1 per cent. of mercury, both cotton-wool and filter-paper were found to fix 0.2 per cent. of the metal. From the determination of the amount of mercury fixed in fibres and that left in the maceration liquid, it would appear that a double action, one of fixing, the other of mere absorption, takes place. Thus jute absorbs 4.77 and fixes 1.69 per cent. of mercury; silk absorbs 6.04 and fixes 1.90 per cent.; wool absorbs 18.25 and fixes 5.89 per cent. With mercuric cyanide solution, containing 1 per cent. of mercury, cotton-wool and paper absorb 1.25 per cent.; kapok, 3.14 per cent.; jute, 3 per cent.; silk, 3.5 per cent.; and wool, 6.05 per cent. of mercury. With mercuric acetate solution, containing 1 per cent. of mercury, cotton-wool absorbs 9 per cent. and fixes 1.5 per cent. of mercury; paper absorbs 7 per cent. and fixes 1.5 per cent.; kapok absorbs 14.5 per cent. and fixes 6.5 per cent.; jute absorbs 12 per cent. and fixes 5.2 per cent.; silk absorbs 17.5 per cent. and fixes 9.8 per cent.; wool absorbs 20.5 per cent. and fixes 12.3 per cent.

Fixing and Absorption of Lead Salts.—Similar results are recorded with lead nitrate solution.

Fixing of Chromic Acid.—From potassium bichromate solution, containing 1 per cent. of chromic trioxide, kapok fixed 0.43 per cent.; jute, 0.53 per cent.; silk, 0.20 per cent.; and wool, 0.69 per cent. of the trioxide.

Absorption of Iodine.—The amount of iodine fixed on the fibres could not be accurately determined. The quantity absorbed was, for kapok, 1.62 per cent.; jute, 2.16 per cent.; silk, 4.19 per cent.; wool, 7.62 per cent.

Behaviour towards Dilute Potassium Nitrate Solutions.—All fibres experimented with were found to have a marked reducing action on potassium nitrate solutions containing 0.001, 0.01 and 0.1 per cent. of NO_3 respectively. Filter-paper had the weakest action, followed by kapok and jute; the animal fibres, silk and wool, were much more active.—J. O. B.

Dyeing; Contributions to the theory of —. Colour Lakes. W. Biltz and K. Utescher. Ber., 1905, 38, 4143—4149.

IT has hitherto been uncertain whether the lakes of organic dyestuffs and metallic oxides are chemical compounds in the ordinary sense, or solid solutions, or "adsorption compounds," and in no case has such a lake hitherto been shown to possess a composition to which an ordinary

stoichiometric formula could be given. The authors have investigated the question by agitation of metallic oxides (hydroxides) with solutions of mordant dyestuffs, both in the cold and at the boiling point of the solvent, and noting the effect of varying concentration of the dyestuff solution when the amount of metallic oxide was kept constant. The amount of dyestuff left in solution was determined colorimetrically, after removal of all suspended matter by filtration, and curves were then constructed showing the concentrations of dyestuff in the lako as ordinates, and concentrations of dyestuff in the final solution as abscissae. In the case of the reaction of iron oxide on a solution of Alizarin in 1 per cent. sodium hydroxide solution in the cold, the results obtained showed that a chemical compound of the formula $\text{Fe}_2\text{O}_3 \cdot 3\text{C}_{14}\text{H}_8\text{O}_4$ is formed. On the other hand the action of boiling aqueous solutions of Alizarin Red S W, on chromium hydroxide led to the production of adsorption compounds. This is borne out by the fact that the results obtained in this latter case agree fairly well with the formula:—

$$\frac{C^{\text{a}}_{(\text{oxide})}}{C_{(\text{dyestuff})}} = K, n \text{ being in, this case, 3, and } K \ 2.1.$$

Further experiments in which the action of ammoniacal and alcoholic solutions of Alizarin and aqueous solutions of Alizarin Blue on iron oxide, and of alcoholic solutions of Gallein on alumina were investigated, did not lead to definite results. The curves obtained end in an almost horizontal portion, but the distance of this from the base line does not agree with any simple stoichiometric formula. Moreover, by comparing these results with those obtained with iron oxide and alcoholic solutions of Alizarin Yellow G G W, Cloth Red G A and Cloth Red 3 G A, the amounts of dyestuff taken up by the same weight of iron oxide were not found to stand in any stoichiometric relation. It was also found that, in all cases investigated, the exact physical condition of the iron hydroxide used influenced the results very greatly. (See also this J., 1905, 920).—E. F.

Dyestuff "Fukugi"; The colouring principle of the Japanese —, and its application to Silk. E. Ito. J. Coll. Engin., Univ. of Tokio, 1905, 2, 267—279.

FUKUGI bark contains a phenolic dyestuff, *fukugetin*, which has been investigated by A. G. Perkin (J. Chem. Soc., 1904, 58; this J., 1904, 56), and to which the author assigns the formula $\text{C}_{20}\text{H}_{16}\text{O}_7$. It crystallises in small light-yellow prisms, having no definite melting point, but decomposing at $274^\circ\text{--}275^\circ\text{C}$., and forms a diacetyl compound melting at $251^\circ\text{--}252^\circ\text{C}$. The bark also contains resins possessing no tinctorial properties. The ordinary method of extracting the dyestuff is to boil 100 kilos. of the bark, in the form of chips, with 180 litres of water, strain, evaporate in a large iron pan till viscid and allow to cool in rectangular moulds. The product is so obtained in hard masses of a yellowish-brown colour; 15 kilos. are said to be obtained from 100 kilos. of bark. The author finds that the dyestuff may be isolated by extracting the bark with lime water or dilute alkali and precipitating with acid; or by extracting with boiling water, precipitating with lead acetate and decomposing with sulphuric acid. The crude dyestuff, obtained by any of these methods may be purified by dissolving in absolute alcohol and precipitating with water. Fukugi may be employed for dyeing either in the form of chips, or as extract, or in two forms devised by the author, "fukugiflavin" and "paste." Fukugiflavin is prepared as follows:—Chips of fukugi bark are thoroughly leached with cold or warm lime water or very dilute alkali solution, strained through calico, boiled with a little hydrochloric or sulphuric acid, and allowed to stand for some days. A yellow precipitate settles. This is repeatedly washed with water by decantation, dried on porous tiles at the ordinary temperature and powdered. The average yield of powder was 6.7 per cent. of the original chips. The "fukugiflavin" thus prepared, has a dyeing power many times superior to that of the ordinary extract. It is converted into paste by wrapping it in a fine cloth, and rubbing in hot water until only coarse particles remain in the cloth, or it may be treated with hot water and strained through calico or a fine sieve. Fukugi dyes silk with

alumina mordant in bright yellow shades; with chrome mordant, olive-yellow shades, with tin mordant, greenish-yellow shades, and with iron mordant, olive-brown shades are obtained. All these dyeings, especially those with chrome mordant, are very fast to soap, sodium carbonate, acetic acid and sunlight, being faster than Mordant Yellow G. More brilliant dyeings are obtained by single-bath methods than by the ordinary methods of first mordanting and then dyeing. Thus a brilliant yellow shade is obtained on silk as follows:—The goods are entered into the dye-bath containing 5 per cent. (on the weight of the goods) of alum, 5 per cent. of acetic acid, 3 to 7 per cent. of fukugiflavin and "a certain quantity" of water, and then heated slowly for an hour to a temperature of $90^\circ\text{--}95^\circ\text{C}$., which is maintained for half an hour. They are then soaped in a 0.5 per cent. soap solution for 15 minutes at $90^\circ\text{--}98^\circ\text{C}$., and finally rinsed.—E. F.

Sulphur Dyestuffs; Printing with —. G. Kögler. Färber-Zeit., 1906, 17, 6—7.

THE Auroral printing colours are mixed with sodium carbonate and a suitable thickening agent and printed; on steaming, sodium sulphide is formed which acts as a reducing agent, e.g., 10—15 parts of Auroral printing paste are mixed with 8—12 parts of calcined sodium carbonate, 15—20 parts of water added, and 20—30 parts of "light-burnt" starch stirred in; the whole is then made up to 100 parts with cold water. The printing paste is passed through a sieve, printed, and the material dried and steamed for from 10 minutes to one hour without pressure, steam as free as possible from air being employed to prevent the formation of oxides of sulphur. After steaming, the material is washed and soaped if necessary.

Caustic soda can be used in place of sodium carbonate, but the printing colours are not so stable, whilst the sodium sulphide which is produced, especially above 20°C ., attacks the printing rollers.—A. B. S.

UNITED STATES PATENTS.

Viscose, &c.; Process and Apparatus for forming Filaments from —. C. A. Ernst, Lansdowne, Pa., Assignor to S. W. Pettit, Philadelphia. U.S. Pats. 808,148 and 808,149, Dec. 28, 1905.

THE solution of viscose is forced into the pipe 3 provided with a perforated cap, which dips into a bath 5 containing a "fixing" liquid. The threads then pass over the smooth rollers 4 and 3, whereby they are subjected to a certain tension, and thence are wound directly on to the spool. The friction rollers are so adjusted that the tension of the portion of the thread between the spool and the tension rollers is greater than that of the portion between the two tension rollers, which is itself greater than that of the threads in the fixing bath.—T. F. B.

Printing Fabrics: Process of —. P. Jeannaire and H. Schmid, Mülhausen, Germany, Assignor to Arnold Print Works, North Adams, Mass. U.S. Pat. 808,987, Jan. 2, 1906.

See Fr. Pat. 329,747 of 1903; this J., 1903, 1044.—T. F. B.

FRENCH PATENTS.

Silk: Process for the manufacture of Artificial —. R. Linkmeyer. Fr. Pat. 357,837, Sept. 18, 1905.

THREADS obtained in the usual way by coagulating jets of a cuprammonium solution of cellulose in neutral or alkaline solutions, are subjected to tension during the subsequent treatment with acids or other agents for the removal of the precipitated copper. It is stated that threads having an excellent lustre and a very silky appearance are obtained in this way.—A. S.

Dyeing Brown by Oxidation, with white or coloured effects; Process of —. Badische Anilin und Soda Fabrik. Fr. Pat. 357,472, Sept. 4, 1905. Under Int. Conv., Dec. 20, 1904.

In the oxidation of *p*-phenylenediamine hydrochloride to produce brown dyes the fibre is always attacked. To remedy this, it is proposed to neutralise the whole or the greater part of the acid by adding sodium formate or acetate, or to use the free base, the oxidation being effected by a chlorate and a trace of a vanadium salt (1 to 10 mgrms. of ammonium vanadate per litre of the bath); the fabrics are steamed after immersion in the bath. These dyes may be easily discharged by means of hydrosulphite compounds, pure whites being obtainable, it is stated. Coloured discharges on brown grounds may also be produced by printing with tannin lakes of basic dyestuffs in conjunction with the reducing agent. A bath may be made up of 30 to 45 grms. of *p*-phenylenediamine hydrochloride, 20 to 30 grms. of sodium acetate, and 1 to 10 mgrms. of ammonium vanadate per litre of water. Homologues of *p*-phenylenediamine give similar results by the above process.—T. F. B.

A REPLY to Rabe and Schliöhs.—J. T. D.

Alkali and Alkaline-earth Carbonates; Decomposition of mixtures of — under the influence of Heat and Vacuum. P. Loebeau. Ann. Chim. Phys., 1905, 6, [8], 433—441. Chem. Centr., 1906, 1, 217.

By heating mixtures of lithium carbonate with barium carbonate and strontium carbonate respectively, the author found that stable compounds of the alkali and alkaline-earth oxides do not exist at 1200° C. The residual alkaline-earth oxide did not contain a trace of lithia.—A. S.

Ferric Sulphate; Formation of a new — from Acid solutions. V. Kolar. Chem.-Zeit., 1906, 30, 15—16.

By concentrating a solution of ferric sulphate $\text{Fe}_2(\text{SO}_4)_3$ in dilute sulphuric acid containing 400 c.c. of sulphuric acid per litre, to 45°—50° B., a white crystalline precipitate is formed of the composition $\text{Fe}^{++}\text{H}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$. When treated with water, the salt dissolves completely after some time, forming a green solution, of slightly acid reaction, which does not act upon potassium permanganate. It is unstable at 100° C., turning brownish and giving off sulphuric acid. At a moderate heat sulphuric anhydride vapours are liberated, ferric oxide being left behind. Solutions oxidised with nitric acid or prepared by anodic electrolytic oxidation of ferrous sulphate yield the same salts.—R. L.

Calcium; Phosphates of —. F. K. Cameron, A. Seidell, and J. M. Bell. J. Amer. Chem. Soc., 1905, 27, 1503—1512, 1512—1514.

THE authors have studied the equilibrium of systems containing calcium oxide, phosphorus pentoxide, and water at 25° C. For concentrations of phosphorus pentoxide between 20 grms. and 317 grms. per litre, the only stable solid phase is calcium hydrogen phosphate, but for higher concentrations up to 550 grms. per litre the stable solid phase is the monocalcium salt $\text{CaH}_2(\text{PO}_4)_2$. In the presence of the dicalcium salt, the concentrations of dissolved phosphorus pentoxide and calcium oxide increase together, from 20:7 to 300:75, but in presence of the monocalcium salt, increase of concentration of dissolved phosphorus pentoxide involves decrease of concentration of dissolved calcium oxide, from 320:77 to 550:35. The curves representing these concentrations meet in a point at which both solids can coexist; and the monocalcium salt can exist in an unstable condition with concentrations of phosphorus pentoxide lower than 317 and of calcium oxide higher than 77 grms. per litre. Agitation of such systems causes rearrangement of the concentrations, with formation of solid dicalcium phosphate. It would appear from these experiments, that the monocalcium salt can never be present in the soil, as the requisite concentration can never be attained. For very low concentrations of phosphoric acid, there seems to be a point, or a narrow range, where the stable solid is tricalcium phosphate, whilst on the higher and lower sides of this, the solid is a solid solution, containing as one of its constituents dicalcium phosphate and lime respectively.—J. T. D.

Potassium Permanganate; Solubility of — in Water. G. L. Voerman. Chem. Weekblad, 1905, 2, 766—767. Chem. Centr., 1906, 1, 124—125.

THE author's results were obtained by titrating the saturated solutions of potassium permanganate in water at different temperatures, with oxalic acid;—

Temperature.	Potassium Permanganate in the solution.	Solid Phase.
° C.	Per cent.	
— 0.18	0.58	Ice
— 0.27	0.99	
— 0.48	1.98	
— 0.58	2.91	Ice and KMnO_4
+ 10	4.01	
+ 15	4.95	KMnO_4
+ 25	7.00	
+ 40	10.40	
+ 50	14.35

Antimony Sulphate and its Double Salts with Alkali Sulphates. S. Metzl. Z. anorg. Chem., 1905, 48, 140—156.

NORMAL antimony sulphate was prepared by dissolving antimony oxide in hot concentrated sulphuric acid, cooling the solution, draining the separated crystals on a porous tile and washing with xylene to remove the last traces of free sulphuric acid. It is not possible to remove the last traces of acid by draining; the crystals previous to the washing with xylene invariably contained a small quantity of free sulphuric acid (about 0.65 per cent. of SO_3). The pure normal sulphate crystallises in silky needles. It is decomposed by water and by alcohol, with formation of basic salts, antimonyl sulphate ($\text{SbO})_2\text{SO}_4$ being produced by the action of cold water, and the basic sulphate $\text{Sb}(\text{SbO})(\text{SO}_4)_2$ by the action of alcohol. By the action of hot water, a more profound decomposition is caused, but it was not found possible to obtain pure antimony oxide except by treatment with alkali, e.g. sodium carbonate. With alkali sulphates, antimony sulphate forms double salts, of the type $\text{M}_2\text{SO}_4 \cdot \text{Sb}_2(\text{SO}_4)_3$, which crystallise in silky needles, and behave in a manner similar to antimony sulphate on treatment with water or alcohol. These double salts are easily soluble in excess of sulphuric acid, and readily crystallise. Their behaviour towards water is of technical importance, since the antimony can be directly extracted from antimony sulphide ores by heating with sulphuric acid in presence of potassium or sodium sulphate. On cooling the resulting solution, crystals of the double sulphate separate, and these can be converted into pure antimony oxide by heating with water and then digesting with sodium carbonate solution.—A. S.

Ammonium Sulphate Statistics. Bradbury and Hirsch, Jan., 1906.

The production of ammonia, calculated into sulphate (including that used for the manufacture of ammonia-soda and for other chemical purposes) from all sources in the United Kingdom during 1905, is estimated at 237,500 tons, made up as shown in the following table, in which the figures for 1903 and 1904 are added for comparison:—

	1903.	1904.	1905.
Gas works	150,000	150,000	151,508
Iron works	19,000	19,500	20,500
Shale works	37,500	42,500	43,000
Coke and carbonising and producer gas works	27,500	33,500	42,500
	234,000	245,500	257,500

Of this total, it is estimated that England contributed 171,400 tons; Scotland, 83,500 tons; and Ireland, 2,600 tons. [T.R.]

Copper Acetate. U.S. Customs Decision, Dec. 19, 1905. MERCHANDISE invoiced as "cuprum acetic crystals" is dutiable at 25 per cent. *ad valorem*, as a "chemical salt," under paragraph 3 of the tariff. The evidence showed that it is largely used by platers, and is distinctly copper acetate, and not a subacetate. It is not known to the trade as verdigris, but is known as verdigris grapes, the crystals being formed on strings suspended in an acid solution. The claim of the importer that it was free of duty as "verdigris," under paragraph 684, was therefore overruled.—R. W. M.

Pyroantimonate of Sodium. U.S. Customs Decision, Nov. 20, 1905.

PYROANTIMONATE of sodium is dutiable as a "chemical salt" at 25 per cent. *ad valorem*, under paragraph 3 of the tariff. The claim of the importer that it was free of duty as "antimony ore," under paragraph 476, was overruled.—R. W. M.

UNITED STATES PATENT.

Lead Hydrate; Method of making —. G. D. Coleman, Boston, Mass. U.S. Pat. 808,141, Dec. 26, 1905.

THE process consists in subjecting to attrition and mixing comminuted metallic lead, water, and a limited quantity of an oxidising agent, in a closed vessel, some of the product being continuously drawn off with some of the water. According to other claims the oxidising agent consists of air, or of air deficient in oxygen, and the temperature of the containing vessel is kept below 100° F. Air is introduced slowly to replace the oxygen consumed in the process, but in such quantity as to maintain the proportion of oxygen present below the proportion in which it is contained in the atmosphere.—E. S.

FRENCH PATENT.

Sulphuric Acid; Furnace for the concentration of — in Porcelain Vessels by means of Hot Combustion Gases and Hot Air, with partial utilisation of the Heat carried by the Acid vapours. H. E. Lemaître. Fr. Pat. 357,553, Sept. 8, 1905.

THE invention relates to improvements in the concentration of sulphuric acid by the system of Négrier (see Eng. Pats., 4171 and 14,022 of 1890; this J., 1891, 46, 639; also this J. 1903, 1346). The furnace is divided into two parts by the supports on which the porcelain basins rest, and the acid is concentrated by the combined effect of hot products of combustion passing below the basins, and hot air (at about 300° C.) passing over the surface of the acid in the basins. The temperature of the acid is kept uniform by maintaining a rapid flow. The hot acid vapours pass through jacketed leaden vessels, in the jackets of which the cold acid to be concentrated is made to circulate, and thus a partial recovery of heat is attained, the acid being raised to a temperature of 80°–100° C. The vapours pass from the leaden vessels to a coke tower. Towards the front end of the furnace, the porcelain vessels are not heated directly by the combustion gases, the concentration of the acid being completed by hot air alone. Means are provided for an interchange of heat between the incoming acid and the hot concentrated acid, and also, in apparatus where two rows of porcelain vessels are used, for feeding equal quantities of dilute acid to each row.—A. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

(Continued from page 73.)

ENGLISH PATENT.

Tiles, Glass, Porcelain and Ceramic Ware, or the like; Apparatus for burning or fixing the Colours upon Printed or Decorated —. L. W. Stanley, Bromley, Kent. Eng. Pat. 28,078, Dec. 22, 1904.

THE object of this invention is to burn and fix colours on glass, ceramic ware, and the like, without using a muffle or saggar, and at the same time to preserve the colours without deterioration. For this purpose a reverberatory furnace is used, heated by hydrocarbon vapours or other combustible gases, burning in air. The hearth, walls, and roof of the furnace are composed of refractory material, and a number of gas jets are arranged on each side of the hearth (which is raised slightly above the actual floor of the furnace), and between it and the walls. The walls and roof are shaped first to direct the gas flames to the centre of the roof, and then to deflect the full heat on to the article to be operated upon. Above and below the furnace two series of chambers are arranged, the former for gradually heating the articles to be burned before inserting them in the furnace, and the latter for gradually cooling them after the burning process.—W. C. H.

UNITED STATES PATENTS.

Glass-Furnace. J. A. Frank, Wellsburg, W. Va. U.S. Pat. 808,358, Dec. 26, 1905.

THE furnace described comprises a melting and refining chamber, from which glass flows through a port or passage to a working chamber. The ends of the melting and refining chamber are connected to a stack, and at the ends of both chambers means are provided for heating them. A flue is situated at a point approximately halfway along the length of the working chamber, to lead products of combustion to a point approximately midway between the outlets of the melting chamber, to insure an even distribution of heat in both chambers. This flue is arranged so as to heat the port or passage for the flow of glass from one chamber to the other.—W. C. H.

Enamelling; Process of —. J. H. Hines, Philadelphia. U.S. Pat. 808,542, Dec. 26, 1905.

IN this process, the article to be enamelled and coloured is cleaned, and placed in an alkaline bath, to prevent corrosion or oxidation of the surface, on which the alkaline matter is allowed to dry. A coat of enamel is then applied to the article, and colouring matter is applied to the enamelled surface, and hurned on to the article in a furnace; and finally another coat of enamel is applied and hurned on.—W. C. H.

FRENCH PATENT.

Silica [Quartz Glass]; Application of Metal to articles of molten —. J. F. Bottomley and A. Paget. Fr. Pat. 357,665, Sept. 12, 1905.

See Eng. Pat. 21,018 of 1904; this J., 1905, 1109.—T.F.B.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

(Continued from page 74.)

ENGLISH PATENTS.

Wood to be Dyed or Impregnated; Method of producing a liquid-tight joint between a Dyeing or Impregnating Vessel, and a block of —. G. Kron, Copenhagen, Eng. Pat., 20,791, Oct. 13, 1905. Under Int. Conv., Jan. 9, 1905.

THE method described consists in casting a ring of readily solidifying material, e.g., lead, round the block of wood to be treated, and subsequently forcing the block against the impregnating vessel, so that the ring forms a liquid-tight joint with it.—W. C. H.

Silicon Carbide; Process for the Manufacture of Forms from —. A. G. Bloxam, London. From Gehrüder Siemens und Co., Charlottenburg, Germany. Eng. Pat. 21,347, Oct. 20, 1905.

THE process consists in mixing carbon with more than sufficient silicon to form silicon carbide—or mixing the ready-formed carbide with silicon—moulding the mixture into the required forms, which are then heated strongly, and preferably in an indifferent atmosphere, until the mass is fritted together. The claims also include forms manufactured by the process.—W. C. H.

Cement; Manufacture of —. The Associated Portland Cement Manufacturers (1900) Ltd., and A. Brooks, London. Eng. Pat. 5763, March 18, 1905.

THIS is an invention for producing a hard slow-setting cement of a green colour. Good white gypsum is treated in the same way as for the manufacture of Keene's cement, and a green colour is imparted to it by the use of chrome alum, or a mixture of potassium bichromate and ammonium sulphate. The mixture of gypsum and chrome alum is baked in the usual way and ground to a fine powder.—W. C. H.

UNITED STATES PATENTS.

Road-Making. J. C. Butterfield, London. U.S. Pat., 808,339, Dec. 26, 1905.

In this process for road-making, suitable available material is reduced, and the finer separated from the coarser material. The finer material is mixed with granulated asphalt, lime or chalk, sodium silicate, and a saccharine substance, to form a substantially plastic mass, capable of setting hard, and into this the coarser material is afterwards firmly embedded.—W. C. H.

Concrete ; Method of mixing ——. P. C. Hains, Washing-
ton, D.C. U.S. Pat. 808,836, Jan. 2, 1906.

THE method of mixing cement consists in wetting the inert material and agitating it in a cloud of dry cement powder, in order to cover the inert material with a cement paste.—W. C. H.

Sand-lime Bricks; Manufacture of ——. A. Gordon, Weiser, Idaho. U.S. Pat. 809,053, Jan. 2, 1906.

The process consists in moulding the sand-line bricks by the wet process, transferring them to pallets, on which they are introduced into a receptacle, where they are subjected to a dry heat, and the receptacle being closed, the bricks undergo a preliminary hardening in the steam generated from the moisture contained in them, the hardening operation being continued by further subjecting the bricks to a moist heat. The apparatus for hardening the bricks comprises a receptacle, provided with a track on which a truck provided with pallets for supporting the bricks in a soft state, is run. The receptacle has a steam jacket, and also a pipe for supplying steam to the interior of the receptacle, and means are provided for supplying steam to the jacket or receptacle at will.—W. C. H.

Paving Stones; Process of manufacturing Artificial —.
W. Schumacher, Oberdollendorf, Germany. U.S. Pat.
809,225, Jan. 2, 1906.

THE process described of manufacturing artificial paving stones, consists in first heating hauxite, with or without the addition of a flux, until it is perfectly sintered, then reducing it to small pieces of suitable fineness, mixing it with a ground binding material, such as clay, cement, asphalt and the like; this mixture is moistened with water and moulded into blocks, which are then burned.

—W. C. H.

FRENCH PATENT.

Siloxicon; Process of making refractory bodies from
—, C. Thorne. Fr. Pat. 357,639, Sept. 11, 1905.
Under Int. Conv., Jan. 6, 1905.

SEE U.S. Pat. 796,459 of 1905; this J., 1905, 971.—T.F.B.

X.—METALLURGY.

(Continued from page 78.)

Cementation Process. A. Ledebur. Stahl u. Eisen, 1906, 26, 72—75.

THOUGH Gay-Lussac, Margueritte, Mannesmann and Roberts-Austen maintained, as the result of experimental work, that cementation occurs through the direct action of solid carbon upon the iron, Guillet has recently upheld the view that it is due to gaseous compounds of carbon, and especially to cyanides, arising from the alkali in the ashes of the charcoal used and the nitrogen of the atmosphere. The author packed bars of Lancashire iron containing 0.144 per cent. of carbon in fresh wood charcoal, previously-used charcoal, and sugar charcoal which had been exhausted with acid, and placed them for 408 hours in the cementation furnace, at a temperature which never exceeded 850° C. The results were as follows:—

	Carbon after Cementation.	Ash of Charcoal.
Fresh wood charcoal	Per cent. 1.45	Per cent. 8.00
Used wood charcoal	1.23	10.75
Sugar charcoal	1.38	0.75

The sugar charcoal ash contained no alkali; yet the action of the sugar charcoal was as marked as that of wood charcoal. The results thus confirm the view that solid carbon is here operative, and that, in the ordinary cementation process, gaseous compounds can play only a very small part.

The experiments indicate a cause for the weaker effect of used than of fresh wood charcoal in cementation. The high ash of the used charcoal arises partly, of course, from the combustion of part of the carbonaceous matter; but it consists partly of sand or firebrick powder from the covering of the box. These, with the alkali of the ash, form fusible glazes which partly cover the charcoal particles and prevent them to that extent from coming in contact with the iron.

Guillet's assertion that, in case-hardening iron, too high a temperature causes decarburisation, is not borne out by facts. Decarburisation will only occur when the supply of carbon is exhausted, and the carbon from the surface of the metal either burns out in the air, if that has access, or migrates towards the interior.—J. T. D.

1997, 1998, 1999, 2000, 2001, 2002, 2003, 2004, 2005, 2006, 2007, 2008, 2009, 2010, 2011, 2012, 2013, 2014, 2015, 2016, 2017, 2018, 2019, 2020, 2021, 2022, 2023, 2024, 2025, 2026, 2027, 2028, 2029, 2030, 2031, 2032, 2033, 2034, 2035, 2036, 2037, 2038, 2039, 2040, 2041, 2042, 2043, 2044, 2045, 2046, 2047, 2048, 2049, 2050, 2051, 2052, 2053, 2054, 2055, 2056, 2057, 2058, 2059, 2060, 2061, 2062, 2063, 2064, 2065, 2066, 2067, 2068, 2069, 2070, 2071, 2072, 2073, 2074, 2075, 2076, 2077, 2078, 2079, 2080, 2081, 2082, 2083, 2084, 2085, 2086, 2087, 2088, 2089, 2090, 2091, 2092, 2093, 2094, 2095, 2096, 2097, 2098, 2099, 2100, 2101, 2102, 2103, 2104, 2105, 2106, 2107, 2108, 2109, 2110, 2111, 2112, 2113, 2114, 2115, 2116, 2117, 2118, 2119, 2120, 2121, 2122, 2123, 2124, 2125, 2126, 2127, 2128, 2129, 2130, 2131, 2132, 2133, 2134, 2135, 2136, 2137, 2138, 2139, 2140, 2141, 2142, 2143, 2144, 2145, 2146, 2147, 2148, 2149, 2150, 2151, 2152, 2153, 2154, 2155, 2156, 2157, 2158, 2159, 2160, 2161, 2162, 2163, 2164, 2165, 2166, 2167, 2168, 2169, 2170, 2171, 2172, 2173, 2174, 2175, 2176, 2177, 2178, 2179, 2180, 2181, 2182, 2183, 2184, 2185, 2186, 2187, 2188, 2189, 2190, 2191, 2192, 2193, 2194, 2195, 2196, 2197, 2198, 2199, 2200, 2201, 2202, 2203, 2204, 2205, 2206, 2207, 2208, 2209, 2210, 2211, 2212, 2213, 2214, 2215, 2216, 2217, 2218, 2219, 2220, 2221, 2222, 2223, 2224, 2225, 2226, 2227, 2228, 2229, 2230, 2231, 2232, 2233, 2234, 2235, 2236, 2237, 2238, 2239, 2240, 2241, 2242, 2243, 2244, 2245, 2246, 2247, 2248, 2249, 2250, 2251, 2252, 2253, 2254, 2255, 2256, 2257, 2258, 2259, 2260, 2261, 2262, 2263, 2264, 2265, 2266, 2267, 2268, 2269, 2270, 2271, 2272, 2273, 2274, 2275, 2276, 2277, 2278, 2279, 2280, 2281, 2282, 2283, 2284, 2285, 2286, 2287, 2288, 2289, 2290, 2291, 2292, 2293, 2294, 2295, 2296, 2297, 2298, 2299, 2300, 2301, 2302, 2303, 2304, 2305, 2306, 2307, 2308, 2309, 2310, 2311, 2312, 2313, 2314, 2315, 2316, 2317, 2318, 2319, 2320, 2321, 2322, 2323, 2324, 2325, 2326, 2327, 2328, 2329, 2330, 2331, 2332, 2333, 2334, 2335, 2336, 2337, 2338, 2339, 2340, 2341, 2342, 2343, 2344, 2345, 2346, 2347, 2348, 2349, 2350, 2351, 2352, 2353, 2354, 2355, 2356, 2357, 2358, 2359, 2360, 2361, 2362, 2363, 2364, 2365, 2366, 2367, 2368, 2369, 2370, 2371, 2372, 2373, 2374, 2375, 2376, 2377, 2378, 2379, 2380, 2381, 2382, 2383, 2384, 2385, 2386, 2387, 2388, 2389, 2390, 2391, 2392, 2393, 2394, 2395, 2396, 2397, 2398, 2399, 2400, 2401, 2402, 2403, 2404, 2405, 2406, 2407, 2408, 2409, 2410, 2411, 2412, 2413, 2414, 2415, 2416, 2417, 2418, 2419, 2420, 2421, 2422, 2423, 2424, 2425, 2426, 2427, 2428, 2429, 2430, 2431, 2432, 2433, 2434, 2435, 2436, 2437, 2438, 2439, 2440, 2441, 2442, 2443, 2444, 2445, 2446, 2447, 2448, 2449, 2450, 2451, 2452, 2453, 2454, 2455, 2456, 2457, 2458, 2459, 2460, 2461, 2462, 2463, 2464, 2465, 2466, 2467, 2468, 2469, 2470, 2471, 2472, 2473, 2474, 2475, 2476, 2477, 2478, 2479, 2480, 2481, 2482, 2483, 2484, 2485, 2486, 2487, 2488, 2489, 2490, 2491, 2492, 2493, 2494, 2495, 2496, 2497, 2498, 2499, 2500, 2501, 2502, 2503, 2504, 2505, 2506, 2507, 2508, 2509, 2510, 2511, 2512, 2513, 2514, 2515, 2516, 2517, 2518, 2519, 2520, 2521, 2522, 2523, 2524, 2525, 2526, 2527, 2528, 2529, 2530, 2531, 2532, 2533, 2534, 2535, 2536, 2537, 2538, 2539, 2540, 2541, 2542, 2543, 2544, 2545, 2546, 2547, 2548, 2549, 2550, 2551, 2552, 2553, 2554, 2555, 2556, 2557, 2558, 2559, 2560, 2561, 2562, 2563, 2564, 2565, 2566, 2567, 2568, 2569, 2570, 2571, 2572, 2573, 2574, 2575, 2576, 2577, 2578, 2579, 2580, 2581, 2582, 2583, 2584, 2585, 2586, 2587, 2588, 2589, 2590, 2591, 2592, 2593, 2594, 2595, 2596, 2597, 2598, 2599, 2600, 2601, 2602, 2603, 2604, 2605, 2606, 2607, 2608, 2609, 2610, 2611, 2612, 2613, 2614, 2615, 2616, 2617, 2618, 2619, 2620, 2621, 2622, 2623, 2624, 2625, 2626, 2627, 2628, 2629, 2630, 2631, 2632, 2633, 2634, 2635, 2636, 2637, 2638, 2639, 2640, 2641, 2642, 2643, 2644, 2645, 2646, 2647, 2648, 2649, 2650, 2651, 2652, 2653, 2654, 2655, 2656, 2657, 2658, 2659, 2660, 2661, 2662, 2663, 2664, 2665, 2666, 2667, 2668, 2669, 2670, 2671, 2672, 2673, 2674, 2675, 2676, 2677, 2678, 26

This lower form, A, Fig. 1, is built to shape in brickwork, with a foundation B for the axis of the template, and a strong, round cast-iron plate C which has four holes to take the bolts E. Around the brickwork is coke-breeze, which allows a ready exit for any gases. The form is lined with loam about 15 mm. thick to within 3 or 4 mm. of the finished thickness, and allowed to dry overnight; it is then made up with fine sifted loam exactly to shape, aided by the rotating template, dried, the hole in the bottom through which the template-axis went is made up, the channels M, Fig. 3, arranged, and the whole dried.

The upper form consists of the channel-ring F and the quadrants G which are belted to it. The quadrants have ventilation-holes as indicated, and projections on the outer surface (see Fig. 4) to hold the loam; the junctions of the flanges are shown in the sectional plan, Fig. 2. The channel-ring has four lugs H for the bolts, 20 holes I through which the metal pours, and eight holes K for the bolts L which fasten the quadrants. The ring is made up with loam, inverted, the quadrants bolted to it and to one another, the template-axis put through the hole N, and the loam worked to within 3—4 mm. of the template; it is then dried, made up to the template with loam, the part O, Fig. 4, of the ring covered, the holes I worked out, the hole N closed by the plate R and filled up with loam, and the whole dried.

The upper form is now set in place, bolted down by the bolts and the bearers S, the pouring-box T, Fig. 5, set in place, and all is ready. The greatest cleanliness is necessary; the metal must be perfectly free from slag or cinder, as any irregularities in the finished pot serve as nuclei for the beginning of action of the soda on it. The pots made in this way are very uniform, and the chilling action of the iron quadrants ensures a close and fine-grained texture.

Silver and Copper Chlorides; Reduction of — by Calcium. L. Haackspill. *Comptes rend.*, 1906, 142, 89—91.

SILVER chlorido and calcium, heated together in *vacuo*, yield alloys containing up to 45 per cent. of calcium. They are grey brittle substances, rapidly oxidising when heated in air, and decomposing water in the cold. Those rich in calcium lose that metal when heated in *vacuo*, but when a certain ratio is reached, calcium and silver volatilise together. Similar alloys of copper and calcium can be obtained in an analogous manner.—J. T. D.

Cuprous Silicide. E. Vigouroux. *Comptes rend.*, 1906, 142, 87—89.

The author has been able to remove from silicon, by successive treatments with nitrohydrochloric acid and hydrofluoric acid, every trace of iron; and from this pure silicon and electrolytic copper has prepared a number of silicides, containing mere or less free silicon. After removing the

latter, the alloy always contained about 10 per cent. of silicon. He has prepared a crystalline silicide by fusing in a stream of hydrogen 90 parts of copper with 17—18 of silicon. The resulting substance, after removing free silicon and fusing in hydrogen, is silver white, with metallic lustre, hard and brittle, with a density of 7.58. Chlorine attacks it readily below a red heat, and acids have but little action on it, save a mixture of hydrofluoric and nitric acids, by which it is oxidised and dissolved. Its composition agrees closely with the formula Cu_2Si .

—J. T. D.

Pyritic Smelting. R. C. Alabaster and F. H. Wintle. *Proc. Inst. Mining and Metall.*, Jan. 18, 1906. [Advance Proof.]

THE authors describe and discuss the process of pyritic smelting (i.e., the smelting of raw sulphide ores in blast-furnaces by using the excess of sulphur as a source of heat) as carried on in various works in the United States. The chief advantages of pyritic smelting over the older method of roasting a portion of the ore to expel the excess of sulphur, are economy of fuel and labour, the estimated saving on these two items being, for fuel, 2 cents per lb. of copper produced, and for labour, 40 cents per ton of ore treated. Further, in pyritic smelting, the fumes from the cupola and converter can be drawn through flues and discharged from a high central stack, so that their injurious effect on vegetation is greatly mitigated, or they may be used for the manufacture of sulphuric acid by the contact process. The chief disadvantage of the process of pyritic smelting is the diminished output for a given set of furnaces.

In applying pyritic smelting to the recovery of gold and silver from ores which are not suitable for the cyanide process, the presence of at least $\frac{1}{2}$ per cent. of copper must be assured. In presence of copper, all the gold can be concentrated in an iron matte, whether it occur in the ore, in the quartz associated with the pyritic mineral, in the gangue, or in the quartz used as flux.—A. Mineral and Metal production of the United States of America. Eng. and Mining J., Jan. 6, 1906.

THE following table, shows the estimated production of the more important minerals and metals in the United States in 1905, as compared with the preceding year. The estimates are made by authorities on substantial data, and, in many cases, are compiled from reports of all, or nearly all, the producers, who have themselves estimated their probable output during the closing days of December:

Mercury industry of California. C. G. Yale. Eng. and Mining J., Jan. 6, 1906.

THERE has recently been over-production of mercury and a decrease in consumption, consequently prices were low and production in 1905 decreased by between 4000 and 5000 flasks.

The consumption in the mining districts of the United States has fallen off materially in late years, notwithstanding the expansion of the mining industry and the rapid increase in the number of properties being worked. The conditions of ore treatment have greatly altered; much more ore is now smelted than was formerly the case. Very few silver mines are now being worked where the pan-amalgamation process is in use. In the bonanza days of the Comstock (when the famously rich ores of the Consolidated Virginia and California were being worked by pan-amalgamation) the loss of mercury per ton of ore was about 7 lb., and naturally, immense quantities were used. In working gold ores, by the ordinary milling process of the present, the loss of mercury is small: it is used, retorted, condensed, and used over again; so that even large mills require only a few extra flasks each year. In some mines, no mercury at all is used. Many other mines ship their ores, carrying gold and other metals direct to the smelters, having no reduction works of their own.

The grade of cinnabar ore, now being worked in California, is much lower than formerly; seemingly, the high grade ore deposits have been exhausted, except where small bunches are occasionally found. Many mines are now working on ore carrying 0.5 per cent. of metal. The Texas mines have ore up to 2.5 per cent., and are doing well. [T.R.]

Antimony industry of America. Eng. and Mining J., Jan. 6, 1906.

THE principal source of antimony in the United States is the hard lead obtained by the desilverising companies. Since its principal utility lies in its combination with lead in bearing and type-metals, the antimony itself is rarely separated from antimonial lead. Whereas hard lead was formerly discounted, as being suitable only for the roughest purposes, it now commands a premium.

The output of hard, or antimonial lead in the United States during 1905 was 11,037 short tons, of which total about 3,000 tons must be assigned to foreign sources. Estimating the average contents at 23 per cent., the total output contained 2,538 short tons of antimony.

Deposits of ore in which antimony constitutes the chief value are not rare in the United States, but, as a rule, they are too remote from transportation and have never been profitable. [T.R.]

Pig-iron and Zinc production of Upper Silesia. Bd. of Trade J., Jan. 25, 1906.

THE "Neue Hamburgische Börsen-Halle" publishes the following statistics of the production of pig-iron in Upper Silesia, issued by the Association of Iron and Steel Producers of Germany (Eastern Group):—

	1904.	1905.
	Metrio tons.	Metrio tons.
Foundry pig	79,229	94,350
Bessemer pig	54,438	47,642
Thomas pig	241,559	258,574
Steel and spiegl iron	83,761	98,112
Puddle iron	86,410	352,884
Total	824,007	881,012

The production of zinc in Upper Silesia amounted, in 1905, to 129,916 tons, as compared with 126,493 tons in 1904. [T.R.]

Chromium and Tungsten &c. U.S. Customs Decision, Dec. 9, 1905.

METALLIC chromium and tungsten are dutiable by similitude to ferro-manganese at 4 dols. per ton, under paragraph 122 of the tariff. The same decision was reached in the case of metallic manganese, molybdenite, and metallic molybdenum, the assessment of duty in all cases as "metals unwrought" under paragraph 183 being overruled, on the ground that iron was present in small quantities, and that the metals in question were not capable of being wrought.—R. W. M.

Iron Oxide. U.S. Customs Decision, Dec. 11, 1905.

THE Treasury Department has ordered an appeal to the United States Circuit from the decision of the Board of General Appraisers, holding that hematite or red oxide of iron is dutiable at 40 cents per ton as "iron ore," under paragraph 121 of the tariff. The Department adheres to the original assessment of duty at 30 per cent. *ad valorem*, as a "pigment or colour" under paragraph 58.—R. W. M.

ENGLISH PATENTS.

Steel; Manufacture of — V. Defays, Brussels. Eng. Pat. 28,570. Dec. 28, 1904.

At the end of each operation the whole contents of the furnace are run out so as to separate the steel from the scoria, after which a portion of the steel is re-introduced while still liquid, either alone or after having been mixed with fresh pig iron. The arrangement facilitates the making of a constant quantity of ingots at each casting, the remainder of the charge being re-introduced so as to form part of a subsequent casting.—J. H. C.

Steel; Manufacture of — R. A. Hadfield, Sheffield. Eng. Pat. 16,385, Aug. 11, 1905. Under Int. Conv., Aug. 13, 1904.

SEE U.S. Pat. 786,561 of 1905; this J., 1905, 677.—T. F. B.

Separating solid particles from each other and apparatus therefor. A. P. S. Macquisten. Eng. Pat. 20,104 and 25,204, Nov. 19, 1904. L. page 112.

Ores or other Substances of different specific gravities; Machines for the concentration of —. G. F. Wynne, Flawgwyn Miners, Denbigh. Eng. Pat. 1697, Jan. 28, 1905.

SEE Fr. Pat. 354,740 of 1905; this J., 1905, 1114.—T. F. B.

Precious Metals; Extraction of — from their Ores. W. H. James, Bedford. Eng. Pat. 27,977, Dec. 21, 1904.

BROMINE, preferably in aqueous solution, together with an oxidising agent, is employed under pressure to dissolve the gold; the excess of bromine is subsequently recovered by evaporation under reduced pressure.—J. H. C.

Ores; Treatment of Auriferous refractory or base —. A. Rollason, Long Eaton, Derby. Eng. Pat. 2286, Feb. 6, 1905.

THE ores are fused or heated with nitrogenous substances (horn cuttings, &c.) in a muffle furnace, excluding the air as much as possible, whereby the gold is reduced to metal, which remains unaffected whilst the foreign substances present are removed by subsequent manipulations.

—J. H. C.

Silvering and Polishing Composition. W. Bülsterh, Winterthur, Switzerland. Eng. Pat. 8359, April 19, 1905.

UNITED STATES PATENTS.

Furnace; Roasting —. F. E. Marcy, Chicago, Ill. U.S. Pat. 808,293, Dec. 26, 1905.

THE furnace has a series of superimposed hearths, and a central hollow rabble shaft having hollow arms operating in the several hearths. A cooling medium is circulated in the shaft through an inlet pipe and a return pipe, and branches or distributing pipes are confined in the hollow arms for conveying the cooling medium from the return pipe through the arms, and back to the return pipe in the shaft. Means are provided for effecting circulation of the cooling medium through the pipes and branches, vertically in series, and "radially consecutively through a multiple." Structural members located within the hearths, and spaced from the furnace walls, support the hollow arms, and are cooled by branches from the pipes carrying the cooling medium.—E. S.

Ores; Process of roasting —. H. Haas, San Francisco, Cal. U.S. Pat. 808,361, Dec. 26, 1905.

ORES are roasted preparatory to smelting, by sintering a mixture of them with a suitable flux, the mixture being subjected, after heating to "the point of ignition of the sulphur or other metalloids," to an evenly distributed light blast of air, continued only long enough to expel and oxidise "the more easily separable metalloid molecules," the heat meanwhile being kept below the smelting temperature. When this process is completed, the supply of air is increased, and is then diminished "as the amount of sulphur and other metalloids remaining to be oxidised decreases."—E. S.

Ores and Metalliferous Sands; Method of applying heat for the treatment of —. W. J. Jackson, San Francisco, Cal. U.S. Pat. 808,754, Jan. 2, 1906.

THE claim is for the addition to ores or metalliferous sands, of a suitable exothermic material, e.g., quicklime, capable of developing heat when the aqueous solution of the extracting agent is applied thereto.—A. S.

Ores [containing Uranium and Vanadium]; Process of treating —. J. H. Haynes and W. D. Engle, Assignors to the Dolores Refining Co., Denver, Colo. U.S. Pat. 808,839, Jan. 2, 1906.

THE ore is crushed, boiled with a solution of alkali carbonate, the solution run off, and the uranium and vanadium separated—the first by precipitation as sodium uranate by sodium hydroxide, and the second as calcium vanadate by slaked lime.—A. S.

Metal; Method of annealing —. W. R. Eachen, Reading, Pa., Assignor to J. T. Williams, Easton, Pa. U.S. Pat. 808,911, Jan. 2, 1906.

THE metal is introduced into a molten mixture of an alkali carbonate (1 part) and sodium chloride (3 parts), and after removal from the bath, is slowly cooled. According to one claim, the annealing mixture consists of an alkali carbonate and two different alkali chlorides.—A. S.

Steam from Hot Slag; Apparatus for generating —. G. Mitchell, Los Angeles, Cal. U.S. Pat. 809,123 and 809,204, Jan. 2, 1906.

SEE Eng. Pat. 2795 of 1905; this J., 1905, 1175.—T. F. B.

FRENCH PATENTS.

[Gold] Ores; Apparatus for grinding or crushing, washing and separating —. R. Stanley. Fr. Pat. 357,771, Sept. 8, 1905. Under Int. Conv., Nov. 10, 1904.

SEE Eng. Pat. 24,386 of 1904; this J., 1905, 1113.—T. F. B.

Furnaces for Burning and Calcining Mineral and other Briquettes. F. J. Bergendal. Fr. Pat. 357,042, Sept. 11, 1905. Under Int. Conv., Feb. 28, 1905.

SEE Eng. Pat. 6388 of 1905; this J., 1905, 958.—T. F. B.

Ores and other Substances; Furnaces for roasting, resulphurising or drying —. A. V. Leggo. Fr. Pat. 357,661, Sept. 12, 1905.

THE furnace comprises a series of horizontal fixed hearths on which the ore is spread. Hollow vertical shafts extend upwards through the hearths and are provided with hollow arms, which, when the shafts are rotated, agitate the ore. Each hearth is furnished with a fire-grate to which hot air is supplied, and a further supply of air for the oxidation of the ore is provided through the hollow shafts and arms. The hot products of combustion mingled with volatile products from the ore pass into a dust chamber where condensable substances and entrained particles of ore are deposited, and thence through flues to the chimney. If desired, the furnace chamber may be closed, and the products of combustion from the fire-grates and the volatile products from the ore discharged through separate flues.—A. S.

Tantalum; Process for hardening soft metallic —. Siemens und Halske Akt.-Ges. Fr. Pat. 357,714, Sept. 14, 1905. Under Int. Conv., Oct. 13, 1904.

SOFT metallic tantalum is hardened by incorporating with it a certain small quantity of another element such as oxygen, hydrogen, carbon, silicon, boron, aluminium, titanium or tin.—A. S.

Briquettes of any Materials; Process for the Manufacture of Hard and Compact —. L. Weiss, Fr. Pat. 357,801, Sept. 16, 1905. II., page 115.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(Continued from page 80.)

(A.)—ELECTRO-CHEMISTRY.

Carbonic Acid; Electrolytic reduction of —. R. Ehrenfeld. Ber., 1905, 38, 4138—4143.

WHEN ammoniacal ammonium carbonate solution (800 grms. of ammonium carbonate dissolved in 3200 c.c. of water, and 880 c.c. of ammonia of sp. gr. 0.910 added) is electrolysed, the anode being of platinum and the cathode (in an inner porous cell) of amalgamated zinc, formic acid is found in the cathode-liquid. In the electrolysis for 12 hours of 300 c.c. of the liquid, with a voltage of 6 to 9 and a current-density of 0.013 to 0.084 ampère per sq. cm., amounts of formic acid varying from 0.1381 to 0.2992 grm. were obtained. Cathodes of iron, nickel, copper, lead, or platinum gave no reduction, nor was any sensible amount of formic acid produced when the electrolyte was diluted 5- or 10-fold. Sodium carbonate, alone

or mixed with hydroxide, when substituted for ammonium carbonate was not reduced; nor was ammonium carbonate alone. Cöhn and Jahn, who obtained formic acid during the electrolysis of a solution of potassium sulphate in a cell, through the cathode-compartment of which a stream of carbon dioxide was passed, concluded that the HCO_3^- ion was reduced; these experiments seem to indicate that the NH_4CO_3 ion is equally susceptible of reduction.—J. T. D.

Incandescence Bodies for Electric Light; Manufacture of [Tantalum] —. Incandescence bodies of Tungsten, Molybdenum or similar Metals; Manufacture of [Electrical] Glow Lamps with —. Siemens and Halske, A.-G. Eng. Pats. 23,097 and 23,098, Nov. 10, 1905. II., page 115.

Incandescent Lamps; Manufacture of light emitting Bodies for Electric —. H. Kuzel. Eng. Pat. 28,514, Dec. 22, 1904. II., page 115.

Electric Storage Battery Negative Pole Plates. A. J. Boulton, London. From E. W. Smith, Philadelphia, U.S.A. Eng. Pat. 839, Jan. 16, 1905.

The active mass of the negative electrode consists of a mixture of inert material (1 to 5 per cent. by weight) and very porous lead oxide, or other lead compound (99 to 95 per cent.) of considerably lower specific gravity than commercial lead oxide. This active material completely fills the cavities in the box-like grid which forms the support. The object of using such material is that its porous and open character enables it to expand within itself without increasing its total bulk, or causing a state of substantial compression.

Roasted lead carbonate, hydrated lead oxide, or their mixtures with lead oxide are quoted as suitable compounds and finely divided lampblack is a satisfactory inert material.—R. S. H.

Electrolysing Apparatus [Bleaching liquors]. E. L. Thorp, Nottingham. Eng. Pat. 25,839, Nov. 28, 1904.

THIS invention relates to apparatus for electrolysing brine solutions for the production of bleaching liquors. The intermediate electrodes divide the electrolytic cell into compartments, which in effect are separate cells. The electrolyte enters at one end at the top, and circulates downwards and upwards to the other end; or it may enter at one side of each and all the compartments, and be discharged from the opposite side. The electrodes are formed of a practically flat sheet of platinum or platinum-iridium, having active sections on one side for the liberation of one gas, and alternating with active sections on the other side for the liberation of a second gas. These sections are obtained by cementing insulating strips alternately on opposite sides of the electrodes, the strips overlapping slightly and forming narrow neutral or non-active portions. Modifications are described in which the neutral portions are slightly bent, so that the insulating strips lie flush with the active surfaces, or each plate may be divided into alternate active squares. In a further modification, horizontal narrow strips of the metal project on each side, and are separated by narrow vertical insulating strips.—B. N.

Nitrogen; Method of and Apparatus for electrically oxidising atmospheric —. H. H. Lake, London. From D. Helbig, Rome. Eng. Pat. 3348, Feb. 17, 1905. SEE Fr. Pat. 352,090 of 1905; this J., 1905, 896.—T.F.B.

Electrodes of Secondary Batteries; Impts. in —. H. M. Levylier. Fr. Pat. 350,332, Nov. 22, 1904.

THIS invention relates to the peroxidation of plates of nickel for use as electrodes. The plate of nickel, previously rendered porous, is used as anode in a concentrated solution of the double nitrate of nickel and ammonium or other alkali base. A similar plate is used as the cathode and the temperature of the bath is maintained near to its boiling point. The current-density is between 0.5 and 1 ampere per sq. dm. of anode surface, and the difference of potential between the terminals about 2 volts. As an electrode, such a peroxidised plate possesses the following advantages; it exerts a relatively feeble resistance; the distribution of current is very regular; its durability is considerable; its specific capacity, referred to unit of mass, is very great.—B. N.

Vanadium and its Compounds; Employment of —, in Accumulators. M. M. J. Bouffort. Fr. Pat. 357,601, Aug. 2, 1905.

LEAD in accumulators is replaced entirely or partly by vanadium, in the form of an alloy, mixture, or oxide. The sulphuric acid in accumulators may also be replaced by the oxy-acids of vanadium or their salts.—B. N.

Filaments for Electric Incandescence Lamps; Manufacture of —. Deutsche Gasglühlicht Akt.-Ges. (Auer Ges.). Fr. Pat. 357,842, Sept. 18, 1905. II., page 116.

(B.)—ELECTRO-METALLURGY.

Tin; Electrolytic deposition of spongy —. D. Tommasi. Comptes rend., 1906, 143, 86.

IN a bath composed of water, 50 parts; stannous chloride, 10 parts; hydrochloric acid, 1 part were arranged two tin anodes and a copper cathode, consisting of a disc, 30 cm. diameter, rotating on an axis above the surface of the liquid, and furnished with rakes for stripping from it and collecting the spongy tin deposited, and at the same time depolarising the surface of the disc. The liquor and washings from the tin are evaporated to the density of the original electrolyte, and returned to the bath. With a current of 40 amperes at 3 volts., 76 grms. of tin were obtained in an hour, or at the rate of "380" grms. per horsepower-hour. (The calculated quantities are "88" and "440" respectively.)—J. T. D.

ENGLISH PATENT.

Metals or Alloys free from Carbon; Electro-Metallurgical manufacture of —. G. Ginz, Paris. Eng. Pat. 8231, April 18, 1905.

THIS process is divided into two operations. In the first

the reduction of the metallic oxides is effected in the presence of a suitable proportion of silica and carbon, with the production of metallic silicides. The second stage of the process consists in using these silicides to reduce a further quantity of metallic oxide, the silicon being eliminated and a metal free from carbon obtained. The latter part of the process can either be carried out on the channel furnace of the author (see Fr. Pat. 342,101 of 1904; this J., 1904, 904), the oxide being introduced on to the surface of the molten silicide; or an arc furnace may be employed with electrodes of cast silicide.—R. S. H.

UNITED STATES PATENT.

Electrodeposition of Metals; Apparatus for the agitation of solutions used in — W. C. Wood and B. Oakford, London, Assignors to W. Canning and Co., Birmingham. U.S. Pat. 808,798, Jan. 2, 1906.

See Eng. Pat. 2001 of 1905; this J., 1905, 1116.—T. F. B.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

(Continued from page 81.)

Oils and Fats; Characteristics of certain foreign — A. Schroeder. Arch. Pharm., 1905, 243, 628—640.

In determining the amount of glycerol in the different fats examined, the author used the acetic method and the recent direct method of Shukoff and Sehestakoff (this J., 1905, 294), the latter yielding the higher results. The indicator, Alkali Blue 6B, recommended by de Negri and Fabris, was used in place of phenolphthalein in the determination of the saponification values of the darker coloured oils. The Reichert-Wolny method was employed in determining the amount of volatile fatty acids, and Helmer's original method for the insoluble fatty acids, whilst the acetyl value was determined by Lewkowitsch's method. In the examination of the liberated fatty acids, Farnsteiner's method (this J., 1898, 804) was used for separating the saturated from the unsaturated acids, and Heintz's method of fractional precipitation for the further separation of the saturated acids.

Oil from the Seeds of Lepidadenia Wightiana Nees — Tangkallak fat.—This tree, which is usually described as *Litsea sebifera*, Bl., *Cyclocodaphne sebifera*, Bl., or *Tetrathera calophylla*, Miq. in older works, is indigenous to Java; but is now found also in the neighbouring islands. The seeds extracted by the author with petroleum spirit yielded 51 per cent. of a hard, nearly white fat, solidifying at about 27° C., and possessing no characteristic taste or smell. It gave the following values:—M. pt., 46·2° C.; spec. grav. at 41° C., 0·8734; saponification value, 268·2; iodine value, 2·28; Reichert-Meissl value, 1·47; Helmer value, 76·05; acid value, 3·35; glycerol, 13·03 per cent.; and unsaponifiable matter, 1·44 per cent. It was judged to have the following composition:—Laurin, 95·96 per cent.; olein, 2·6 per cent.; free fatty acids, 1·67 per cent.; and unsaponifiable matter (which gave the phytosterol reaction), 1·44 per cent.

Oil from the Seeds of Strychnos Nux Vomica.—The author's results are very similar to those obtained by Harvey and Wilkie (this J., 1905, 718):—Saponification value, 160; iodine value, 64·2; Reichert-Meissl value, 1·76; Helmer value, 94·86; acid value, 27·4; acetyl value, 42·23; glycerol, 8·67 per cent.; and unsaponifiable matter, 16·93 per cent. The amount of oil extracted by means of ether from the seeds was 4·2 per cent. It was deep green in colour, fluorescent, and had an extremely

bitter taste. Solid glycerides separated out at the ordinary temperature, but the fat did not liquefy completely until 28° C. was reached. The specific gravity at 20° C. was 0·8826. The average of all the results obtained were the following for strychnos oil, viz., 16·93 per cent. of unsaponifiable matter, 8·6 per cent. of solid glycerides, 74·47 per cent. of olein (with which were calculated the volatile acids), and 13·79 per cent. of free fatty acids (calculated as oleic acid). Arachidic and palmitic acids were identified in the solid fatty acids. The unsaponifiable matter contained phytosterol, a substance resembling colophony, and 3·18 per cent. of strychnine and hucine. The oil, after removal of the alkaloids, had a saponification value of 166·2 and an iodine value of 69·4.

Oil from the Seeds of Hevea Brasiliensis.—Oil from Seed of Para Rubber Tree.—The seeds examined by the author yielded 27·5 per cent. of a clear light yellow oil on extraction with petroleum spirit. The bulk of the seeds, however, on extraction with ether gave 24·3 per cent. of a deep green semi-solid oil, which became completely fluid at about 26° C., but at 21° C. yielded a deposit of solid glycerides. It gave the following values:—Specific gravity at 20° C., 0·9293; saponification value, 198·23; iodine value of oil extracted with petroleum spirit, 127·9; iodine value of oil extracted with ether, 117·49; Helmer value, 95·06; acid value, 57·4; acetyl value, 27·9; glycerol, 9·49 per cent.; and unsaponifiable matter, 0·705 per cent. Volatile fatty acids were absent. The insoluble fatty acids solidified to a butter-like mass at 15° C., and had a mean molecular equivalent of 283·3 and an iodine value of 127·20. They were found to contain stearic and palmitic acids.

Oil from the Root of Polygala Senega, L.—10 kilos. of the root extracted by Gehe and Co. yielded 4·65 per cent. of a thick deep brown oil with a bland taste and slightly rancid odour. It was readily soluble in ether, chloroform, benzene, acetone, and carbon bisulphide, with more difficulty in alcohol and xylene, and left a portion completely insoluble in petroleum spirit. It had the following values:—Sp. gr. at 18° C., 0·9616; saponification value, 193·61; iodine value, 82·05; iodine value after separation of unsaponifiable matter, 78·61; Reichert-Meissl value, 6·43; Helmer value, 85·8; acid value, 37·9; acetyl value, 44·46; glycerol, 8·3 per cent.; and unsaponifiable matter, 12·78 per cent.

The unsaponifiable matter was found to consist, in the main, of resinous substances remaining undissolved on treating the oil with petroleum spirit. The separated oil was clear and of a brownish-yellow colour. Salicylic acid separated from the distilled volatile fatty acids on standing. The insoluble fatty acids were separated by Farnsteiner's method into saturated and unsaturated acids. The latter had an iodine value of 82·4, and therefore were judged to contain no more highly unsaturated acid than oleic acid, the presence of which was confirmed by the elaidin test. The saturated fatty acids melted at 52° C., and, after repeated crystallisation at 61° C. The presence of palmitic acid was proved, and the oil was calculated to have the following composition:—Unsaponifiable constituents, 12·78; palmitin, 7·93; and olein, 79·29 per cent., the latter including the volatile fatty acids and the free fatty acids, calculated as oleic acid.—C. A. M.

Fats; Characteristics of certain Animal — C. Schneider and S. Blumenfeld. Chem.-Zeit., 1906, 30, 53—54.

The methods of determining the different constants of these fats were those ordinarily employed, Lewkowitsch's method being used for the determination of the acetyl value. The following results were obtained:—

Fats.

With regard to these results, the author points out that the iodine value of the fat of the lynx is the highest yet recorded for the fats of terrestrial beasts of prey.

—C. A. M.

Surin Fat. J. Lawkowitsch. Analyst, 1906, 31, 2—3.

A sample of fat from Porak, marked "Minyak surin," probably derived from seeds of a species of *Palagium*, gave the following results after filtration:—Free fatty acids, 43.2 per cent.; sp. gr. (60°/60°) 0.9021; solidification commences, 48.9° C., and is complete at 43.9° C.; m.pt., 56.1° C.; saponification value, 179.5; unsaponifiable matter, 4.54 per cent.; iodine value, 42.31 per cent.; Reichert-Wollny value, 0.55 per cent. The fatty acids, which consisted mainly of stearic and oleic acids, had a solidifying point of 59.1° C., mean mol. wt., 284.9, and contained 58.2 per cent. of stearic acid (m.pt. 67.8° C.). The fat would seem to be useful as a raw material in the candle industry on account of its high percentage of stearic acid, although the rather high amount of unsaponifiable matter might militate against this; this latter, however, is possibly due to faulty preparation. The fat differs considerably from that of *Palagium oblongifolium*, described by De Jongh and Tromp. The retention of its native name "Surin fat" is suggested, at any rate until its true source is known.—T. F. B.

FRENCH PATENT.

Soap Solution; Apparatus for cooling ——. Krefelder Seifenfabrik, Stockhausen and Traiser. Fr. Pat. 357,637, Sept. 11, 1905.

The apparatus consists of a cylindrical vessel with a conical bottom and surrounded by a jacket, in which the refrigerating liquid circulates. A small tube, also filled with refrigerating liquid, passes down the centre of the vessel, and around this tube is fitted a helical mixing device. An opening at the bottom of the vessel is provided for the removal of the soap.—W. P. S.

Gelatin spontaneously rendered insoluble in darkness; Composition of Bichromated ——. A. I. Lumière and A. Seyewetz. Bull. Soc. Chim., 1906, 35, 14—16.

GELATIN was immersed in a 3 per cent. solution of potassium bichromate, and then placed in a dark chamber (a) at the ordinary temperature and (b) at 120° C., until it could be submitted to treatment with water at 80° C. without melting. In the first case the gelatin became insoluble after 4½ months, when it was colourless, and contained 1.15 per cent. of chromic oxide, none of which could be extracted by ammonia; on the other hand, the gelatin kept at 120° C. became insoluble after six days, and had the same appearance as if it had been kept in the light: it contained 20.59 per cent. of chromic oxide and 2.72 per cent. of the chromic acid radical; this gelatin became disintegrated by boiling water though not dissolved, being reduced to particles so fine as to pass through a filter. The gelatin treated at the ordinary temperature did not completely resist the action of boiling water. (See this J., 1905, 1125.)—T. F. B.

"Foamine." U.S. Customs Decision.

FOAMINE, an extract obtained from the horse chestnut by boiling with caustic soda solution, was classified for duty at 25 per cent. *ad valorem* as a "chemical compound." The importers claimed it to be a "drug advanced in value or condition," and hence dutiable at 1 cent per lb. and 10 per cent. *ad valorem*. The Board of General Appraisers disposed of this claim by ruling that the horse chestnut is not a drug, and expressed the view that the foamine is dutiable as a "manufactured article unenumerated" under section 8 of the tariff.—R. W. M.

["Sichel" Glue. U.S. Customs Decision, Nov. 13, 1905.

An article invoiced as Sichel glue, consisting of water, starch, dextrin, and vegetable gum, is not dutiable as "glue" under the rates provided under paragraph 23 of the tariff. The article is used by painters for sizing walls and as a binding agent in calcining, and is dutiable at 20 per cent. *ad valorem*, under section 6 as a "manufactured article unenumerated."—R. W. M.

ENGLISH PATENTS.

Hides; Treatment of —, and the manufacture of Tyres or Tyre Covers therefrom. R. Withey, London. Eng. Pat. 8514, April 20, 1905.

THE raw hide is soaked in water for three to seven days, then "blubbered," and afterwards placed in a pit with lime-water for a similar period. The hair is now removed and the hide steeped in a mixture of alum and egg albumin for four to ten days. The hide is then placed in a series of baths containing solutions of sulphuric acid, "red arsenic" (realgar), and sumnac, of increasing concentration; about four of these baths may be used, the hide being left in each for twelve hours. It is now placed for two days in a bath containing rubber solution, benzene and naphtha, and finally strained on frames and dried. The hide may be soaked in benzene and naphtha, and the rubber solution afterwards worked into it. Hide thus prepared may be used in the form of a strip, or strips, between the outer rubber cover and the canvas lining of tyres, or it may be attached to the exterior of the cover, or to the rim of the wheel.—W. P. S.

Leather; Process of preparing [Waterproofing, &c.] —. P. Magnus, Northcote, and T. J. Davis, North Fitzroy, Australia. Eng. Pat. 10,443, Sept. 26, 1905.

THE leather is dried, buffed up on the flesh side, and treated with a mixture consisting of a 4 per cent. solution of sulphur chloride in carbon bisulphide, 10 parts; benzol, 10 parts; ether, 4 parts; benzine, 3 parts; "naphtha," 8 parts; turpentine, 2.5 parts; and kerosene 2.5 parts. The leather is redried at a temperature of 100° F., and then steeped for 48 hours in a mixture of Para rubber, 6 parts; "naphtha," 68 parts; benzine, 24 parts; and benzol, 2 parts. This mixture is worked into the leather, which is then dried and again steeped in the solution. The leather is now placed in a revolving drum containing rubber solution, in which the amount of "naphtha" is increased. It is left in this mixture for a further 24 hours, then semi-dried, rolled, and finally completely dried. (See also Eng. Pat. 7492 of 1903; this J., 1903, 1201.)—W. P. S.

FRENCH PATENTS.

Tannin; Method and Apparatus for the continuous extraction of —. G. F. Bügel. Fr. Pat. 357,647, Sept. 7, 1906.

THE apparatus consists of a series of upright cylinders, the top of each one being connected by a pipe with the bottom of the next. In each of the connecting pipes is a steam injector. Through each cylinder passes a central tube, in which an endless screw works. The tanning material to be extracted is fed in at the top of the first cylinder, and is carried up the central tube by the endless screw, and discharged into the top of the second cylinder, and so on, whilst water is caused to flow through the series of cylinders in the opposite direction. At each end of the series of cylinders is a centrifugal machine, one for drying the spent tanning material, and the other for separating solid particles from the tannin liquor.—W. B. H.

Leather; Oil for the Preservation of —. H. Schowalter. Fr. Pat. 357,525, Sept. 6, 1905.

THE composition claimed for the preservation of leather consists of fish oil mixed with a solution of three parts of caoutchouc in 100 parts of turpentine, and 1½ parts of aniline oil.—W. B. H.

(Continued from page 85.)

Starches other than Potato Starch; Reversion and composition of —. E. Roux. Comptes rend., 1906, 142, 95—97.

THE author has tested starches of various kinds in a manner similar to that described for potato starch (this J., 1905, 630). When the starch pastes prepared at 100° C. were converted by malt extract at 56° C. under the most favourable conditions, the following yields of maltose, calculated on the weight of dry starch dissolved, were obtained:—Potato, 83.0; maize, 83.3; wheat (paste prepared at 150° C.), 87.1; rice, 85.2; pea, 83.8; tapioca, 81.5 per cent. The differences in maltose yields from pastes prepared at 120° and 150° C., as compared with those prepared at 100° C., were very slight. All these starch pastes reverted, with separation of amylocellulose in the insoluble condition, when allowed to remain at the ordinary temperature. The various specimens of amylocellulose so produced were purified by repeated solution and reversion, and their solutions, prepared with water at 155° C., were converted by malt. Yields of maltose

ranging between 100 and 102 per cent. of the dissolved starch were obtained. Hence it is concluded that all starches resemble potato starch in being composed of amylocellulose and amylopectin in practically constant proportions.—J. F. B.

Invertase; Action of — in a heterogeneous medium.
V. Henri. *Comptes rend.*, 1906, 142, 97—100.

THE laws of the action of enzymes enclosed in plant cells upon substances diffusing into the cell from the plant juice, are very different from those which regulate the action of enzymes upon substances in homogeneous solution with them. The author has studied the action of invertase upon cane sugar when the two bodies are separated by a permeable membrane. Invertase was dissolved in a 10 per cent. solution of gelatin melting above 40° C. This solution was spread in known quantity over the bottom of a flat-bottomed flask of given area. The jelly was allowed to solidify, and a film, 1 mm. thick, of pure gelatin at a higher concentration was poured over the surface of the jelly in order to represent the cell membrane in the plant. Solutions of cane sugar were then placed in contact with the gelatin, and the rates of inversion were studied for different concentrations and at different temperatures. The results showed that the rate of inversion under these conditions was nearly proportional to the concentration of the cane sugar solution, whereas when the ferment and sugar are present in the same solution, the rate of inversion is nearly independent of the concentration of sugar. In other words, the rate of ferment action in a heterogeneous medium is proportional to the rate of diffusion through the separating membrane. Further, it was found that a change in the temperature had less influence on the rate of inversion in the heterogeneous medium than in the homogeneous solution, owing to the fact that, whereas a rise of temperature of 10° C. accelerates a chemical reaction by about 100 per cent., it only accelerates the rate of diffusion by about 25 per cent.—J. F. B.

Beer; Dantzig Jopen —. P. Mummé. *Woch. f. Bran.*, 1906, 23, 13—16.

JOPEN beer is a heavy gravity top-fermentation beer prepared at Dantzig, and also at one place in England; it is characterised by a peculiar flavour and odour of port wine, and is used for making sauces and as a tonic. The quantity produced is very small, and is on the decrease. Jopen beer is brewed only in the winter months, preferably from fresh malt. The mashing process generally adopted is the triple decoction process, and about $\frac{1}{2}$ lb. of hops are used per cwt. of malt. The wort is prepared in a very concentrated state, and undergoes further concentration during the boiling to such a degree that, after cooling, it has a gravity corresponding to 50—54 per cent. of extract. The wort is cooled in the cooler-back almost to 0° C., and is then passed to the fermentation tuns, in which it is allowed to ferment spontaneously. The wort remains quiet for a considerable time, during which a thick film forms on the surface; this film varies in appearance in different batches. Fermentation sets in gradually, and as the film rises it should be skimmed off; the foam which overflows is collected and the beer is returned to the tun. After a few days, the fermentation dies down and gives place to a quiet secondary fermentation. The beer is allowed to remain in the tuns and slowly clears; this stage of the process may last for a year. In some breweries cask-fermentation is adopted, in which case the frothing over during primary fermentation rarely occurs. In the following autumn the matured beer is strained and packed in small casks of 13 litres capacity, and is exported; it is frequently stored for another year before consumption. An analysis of a typical Jopen beer showed:—Alcohol, 3.52; apparent extract, 43.20; real extract, 46.04; calculated original wort extract, 49.94; apparent attenuation, 13.49; actual attenuation, 9.81 per cent. The species of yeast concerned in the fermentation of this peculiar type of beer has not been definitely determined. Ländner has suggested *S. Buxii*, but possibly a mould fungus may be the active organism.—J. F. B.

Arsenic in Wines; Occurrence of —. H. D. Gibbs and C. C. James. *J. Amer. Chem. Soc.*, 1905, 27, 1484—1496.

THE authors have examined 329 samples of wine, in 88 of which they found arsenic. Bottled wines and wines from the wood equally contained it. The largest amount at first found was 1 part in 20 millions; though (as stated in a footnote) in later samples larger amounts, up to 1 part in 2½ millions, were present. Probably arsenic never occurs in wines in quantity sufficient to exert any toxic action; but the quantities which do exist are accidental, and can probably be excluded. No one source will account for what has been found; but the most probable sources are arsenical sprays used upon the vines, sulphur burnt for the purpose of sulphuring the wine, and receptacles. In the case of bottles, lead shot used in cleaning them may sometimes be the cause.—J. T. D.

Starch and Amylocellulose; Determination of coagulated —. J. Wolff. *XXIII.*, page 139.

Hordeine; A new Alkaloid from Malt culms. E. Léger. *XX.*, page 133.

Beer production in Austria. Bd. of Trade J., Jan. 26, 1906.

THE production of beer in Austria from 1st September, 1904, to 31st August, 1905, was 19,008,540 hectol., as compared with 19,820,590 hectol. in the previous year. The duty paid to the Government on the same amounted to 3,042,603*l.*, as compared with 3,133,102*l.* Bohemia is the principal beer-producing district of Austria. [T.R.]

Saké; Japanese —. U.S. Customs Decision, Nov. 22, 1905.

THE Treasury Department has ordered an appeal to the United States Circuit Court from the decision of the Board of General Appraisers of October 20th, which followed a decision of the United States Circuit Court of Appeals in making saké dutiable at 20 per cent. *ad valorem* under Section 6 of the tariff, as a "manufactured article unenumerated."—R. W. M.

Lactic Ferment. U.S. Customs Decision, Nov. 15, 1905.

AN article known as Danish lactic ferment is not dutiable, as assessed, at 20 per cent. *ad valorem* as a "manufactured article unenumerated" under section 6 of the tariff, but at 5 cents per lb., as "sugar of milk" under paragraph 239, sugar of milk being the component material of chief value.—R. W. M.

UNITED STATES PATENT.

Beer; Process of Pasteurising —. C. H. Loew, Lakewood, Ohio. U.S. Pat. 808,668, Jan. 2, 1906.

THE bottles of beer are placed in a suitable chamber, and are subjected to the action of a spray of water, the temperature of which is gradually raised to the necessary point. The desired temperature is maintained for a sufficient length of time, and the water serving for the spray is then gradually cooled to the normal temperature. The water discharged from the spray is collected, after passing over the bottles, in a reservoir at the bottom of the chamber, which is provided with heating and cooling coils, this reservoir also serving to supply water to the spraying devices.—J. F. B.

FRENCH PATENT.

Filters for Wine and other liquids. Soc. A. Dupoux, L. Gibaud et Cie. Fr. Pat. 357,849, Sept. 19, 1906.

THE filter consists of a cylindrical casing covered with a tid. In this casing are placed a number of superposed baskets each of which is divided by a vertical spiral partition, which starts from the centre and ends at the periphery. The filtering material consists of a tubular cloth bag disposed in the spiral channel of each basket. The ends of this bag are tied to the supply ducts for the crude liquor, one of which enters at the centre, and the other at

the periphery. The crude liquor contained in a high-level reservoir enters the spiral bags at each end under pressure, and the filtered liquid, which percolates through the cloth walls, passes through distributing pipes situated in the cover of suitable receptacles.—J. F. B.

ENGLISH PATENTS.

Separators for Liquids (Milk); Centrifugal ——. Aktiebolaget Separator, Stockholm. Eng. Pat. 27,875, Dec. 20, 1904. Under Int. Conv., Dec. 21, 1903.

The liquid (milk, &c.) to be separated is fed by a central vertical pipe into a horizontal ring or set of radial distributing arms, carried by the pipe and fitting into a recess formed by cutting notches on the inner edges of the curved dividing plates of the separator, at a point about midway between the upper and lower edges of the plates. In an alternative form, the central pipe extends to within a short distance from the bottom of the drum or bowl, and ends in a flange which extends into a recess formed by cutting notches on the inner edges of the plates at the bottom. The object in each case is to deliver the liquid to be separated into the neutral zone between the cream and skim-milk which collect at the inner and outer edges of the curved plates.—W. H. C.

Separators for Liquids (Milk); Centrifugal ——. Aktiebolaget Separator, Stockholm. Eng. Pat. 27,876, Dec. 20, 1904. Under Int. Conv., Dec. 21, 1903.

The claim is for a "division contrivance" to be placed within the drum of the separator, and consisting of a series of vertically arranged curved plates. The upper and lower edges of the plates are bent so as to form flanges, in order to partially close the spaces between the edges of adjacent plates, with the object of checking the escape of the liquid. The outer edges of the plates, which fit into notches or grooves on the inner wall of the drum, may also be bent into flanges to increase the separating effect, and the inner edges may be bent into hooks so that the plates engage with, and keep one another in position.—W. H. C.

Butter; Process and Apparatus for the preservation of natural ——. A. Dobinsson, Brussels. Eng. Pat. 28,374, Dec. 27, 1904.

The butter is melted in a tubular apparatus heated to a temperature of 50° C. The melted fat as it flows from this part of the apparatus is led into a water-bath, and from the latter to a separator, where it is kept at a temperature of 40° C., and the complete separation of the curd takes place. From the separator, the clear fat is led into a water-bath where it is allowed to remain for one hour, and is then poured into barrels to be stored. For "reconstituting" the butter, the melted fat is conducted directly from the water-bath to a churn, where it is emulsified with sterilised water or milk at a temperature of about 35° C. The emulsion as it leaves the churn meets jets of cold water. The solidified butter is then separated from the water, placed in a refrigerating chamber for 12 hours, and then treated in the usual way. The fat may be sterilised on leaving the separator or the water-bath. (See also U.S. Pat. 784,394 of 1905; this J., 1905, 341.) —W. P. S.

UNITED STATES PATENT.

Milk Preserve and Process of making same. L. Sarason. Berlin, Assignor to C. F. Boehringer und Soehne, Mannheim-Waldhof, Germany. U.S. Pat. 800,138, Jan. 2, 1906.

Milk, which is prepared so as to contain a substantial

amount of living lactic-acid germs, such as buttermilk, is evaporated to dryness at a temperature not exceeding 60° C., and the dry product is powdered.—J. F. B.

FRENCH PATENT.

Food Product from Milk, especially suited for Infants, and Process of making same. J. R. Hatmaker. Fr. Pats. 357,790, and 357,800, Sept. 16, 1905. Under Int. Conv., Sept. 21, 1904.

See Eng. Pats. 20,339 and 20,340 of 1904; this J., 1905, 981.—T. F. B.

FRENCH PATENT.

Pulp Strainers. L. Kruse. Fr. Pat. 357,891, Sept. 20, 1905.

In rotary cylindrical pulp strainers, consisting of a horizontal slotted drum revolving in a trough containing the crude pulp at a higher level than the strained pulp, the latter is discharged through a hollow axis at the end of the drum. The present invention relates to the packing of the joint between the revolving hollow axis and the fixed part of the trough containing the crude pulp. The latter is tapered off in the form of a funnel, through the narrow part of which the hollow revolving axis passes. A conical flap of rubber is attached to the conical funnel, and is pressed, by the pressure of liquid, against an adjustable ring fixed to the hollow axis, thus making a tight packing.—J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(Continued from page 90.)

Quinine Trade in 1905. Pharm. J., Jan. 20, 1906.

DURING 1905 the estimated contents of the cinchona bark sold at Amsterdam and the London sales amounted to 12,000,000 oz., of which only 1,100,000 oz. were sold at the London auctions. 335 tons of quinine thus passed into currency last year. The estimated contents of quinine in the bark sold at the ten sales in Amsterdam and at 112 sales in London during the last six years were as follows:—

	In Amsterdam.	In London.
	Ounces	Ounces.
1900	8,800,000	2,000,000
1901	11,500,000	1,800,000
1902	11,300,000	1,400,000
1903	11,680,000	1,150,000
1904	13,100,000	650,000
1905	10,900,000	1,100,000

The stock of quinine in London on December 31, 1905, was 2,806,000 oz., compared with 3,336,000 oz. in 1904; 3,206,000 oz. in 1903; 3,594,000 oz. in 1902; 3,557,000 oz. in 1901; 3,356,000 oz. in 1900; 2,793,000 oz. in 1899.

The average percentage of quinine in the manufacturers' bark offered in Amsterdam has not varied much, the lowest average being 5.21 in 1898, and the highest 5.49 in 1905. The richest bark offered last year contained a percentage equivalent to 13.08 of sulphate; this was a parcel of 16 bales of Ledgeriana stem. On the other hand, the average unit paid has varied very considerably. At the January sale in 1897 the unit dropped to 2.12, while in September, 1900, it reached 12.25. Since the June auction last year the average unit has gradually fallen from 6 to 5.80 in July, 5.75 in August, 5.55 in September, 5.20 in October, 4.75 in December, and 4 in January, 1906.

[T. R.]

Hordenine; A new Alkaloid from Malt culms. E. Léger. Comptes rend., 1906, 142, 108—110.

This alkaloid has been extracted from malt culms by means of Stas' method, and was purified by repeated crystallisations from alcohol. Hordenine is obtained as colourless, anhydrous, orthorhombic prisms, almost tasteless, melting at 117.8° C. (corr.). When heated above its melting point it sublimes like camphor; its solutions have no action on polarised light. Hordenine is readily soluble in alcohol, chloroform and ether, less soluble in benzene, very sparingly soluble in toluene and xylene, and nearly insoluble in petroleum hydrocarbons. It is a strong base, reacting as an alkali towards litmus and phenolphthalein and capable of displacing ammonia from its salts. It reduces permanganate in acid solution in the cold, and ammoniacal silver nitrate and iodic acid on warming. Hordenine has a composition and molecular weight corresponding to the formula $C_{10}H_{15}NO$; it is a mono-acidic, tertiary base and the oxygen has a phenolic character. A series of salts and alkyl and acetyl derivatives are described. The alkaloid is soluble in solutions of caustic alkalis, and the solution of the sulphate is coloured slightly violet-blue by ferric chloride. Hordenine has been found to be slightly toxic, causing death by affecting the respiration when administered to animals in relatively large doses.—J. F. B.

Hyoscyamus Oil; New method for the Preparation of [Infused].—A. Raethje. J. Pharm. v. Pflanz.-Lothring., 1905, 193. J. Pharm. Chim., 1906, 23, 65—66.

Four comparative experiments were made:—(1) One grm. of stearic acid was dissolved in 250 grms. of (olive) oil and 25 grms. of hyoscyamus leaves were infused in the solution for 10 days at the normal temperature; the liquid was then strained, the residue pressed,

and the oil filtered. It contained 0.0046 per cent. of alkaloids. (2) One grm. of stearic acid was dissolved in 20 grms. of alcohol; 25 grms. of the leaves were moistened with this mixture and left, in a covered vessel, for two hours; the mixture was then heated on the water-bath with 250 grms. of (olive) oil until the alcohol had evaporated. It was then strained, pressed, and filtered. It contained 0.0052 per cent. of alkaloids. (3) Twenty-five grms. of leaves were heated on the water-bath for two hours, under a reflux condenser, with 100 grms. of alcohol and 1 grm. of stearic acid, and then treated as in No. 2. The alkaloidal content of the finished product was 0.0075 per cent. (4) This was prepared according to the official directions of the Ph. C. IV. (moistening the leaves with alcohol, macerating in the cold with oil, then evaporating off the alcohol on the water-bath.) It contained 0.0048 per cent. of alkaloids.—J. O. B.

Hyoscyamus Oil; Preparation of [Infused].—W. Kuntz. Apoth.-Zeit., 1905, 20, 857. J. Pharm. Chim., 1906, 23, 66.

THE crushed hyoscyamus leaves are macerated for 24 hours in a closed vessel with 90 per cent. alcohol containing 2 per cent. of ammonia solution (sp. gr. 0.980). The mixture is then treated with 6 parts of olive oil and heated on the water-bath for 10 or 12 hours until the alcohol and ammonia are completely driven off. After decantation and pressing, the expressed mass is again extracted in a similar manner with another 4 parts of oil. The bulked oil extracts yield a product containing 0.068 per cent. of alkaloids. (See also preceding abstract.)—J. O. B.

Medicinal Plants; South African.—[Umjela (Tabernaemontana ventricosa); Buphane toxicaria; Acanthera venenata; Polygonum tomentosum.] C. F. Juritz. Trans. S. Afric. Phil. Soc., 16 [2], 111. Pharm. J., 1906, 78, 87.

THE author describes the properties and some of the constituents of a number of South African medicinal plants. From the bark of the "Umjela" or quinine tree (*Tabernaemontana ventricosa*, Hochst.) 0.2 per cent. of an alkaloid crystallising in needles was obtained, which was not identical with quinine or any other alkaloid of the cinchona group. From the bulb of *Buphane toxicaria*, Herb., 0.4 per cent. of an alkaloid resembling hucine in its physiological action, but differing from the latter in chemical properties, was obtained. The active principle of *Acanthera venenata*, Don., is an uncrystallisable glucoside, which gives with concentrated sulphuric acid, a yellow colour changing successively to pink, brick-red, and violet. The dried root of *Polygonum tomentosum*, var. *glabrum* contains 2½ per cent. of an acid resin, which gives with sulphuric acid a pinkish-yellow colour, changing successively to cherry-red, deep crimson, and dirty brown, and finally fading to a greenish tint.—A. S.

4. Amino-antipyrine; Synthetic Bases from —, M. Luft. Ber., 1905, 38, 4044—4049.

ONE molecule of ethylene bromide is heated with 2 molecules of aminoantipyrine and a little alcohol on the water-bath. On adding caustic alkali and cooling, diantipyrine-diethylenediamine crystallises out. If the filtrate is evaporated, diantipyrine-ethylenediamine

$C_{11}H_{11}N_2O.NH.CH_2.CH_2.HN.C_{11}H_{11}N_2O$, separates as a yellow oil. From chloroform and ether it is obtained as a colourless flocculent powder, m. pt. 54° C. The picrate crystallises from alcohol in yellow needles, m. pt. 182° C. The base is not changed by alkalis. With ethylene bromide it passes into diantipyrine-diethylenediamine:—

This base is soluble with difficulty in most solvents. From alcohol it crystallises in nearly colourless tablets, m. pt. 202° C. Antipyrine-piperidine

is formed when aminoantipyrine and 1,5-dibromopentane are heated on the water-bath. After several crystallisations

tions from ether, it forms colourless needles, smelling like piperidine and melting at 144° C. The picrate separates from ether in yellow prisms, m. pt. 198° C. with decomposition. Antipyril-tetrahydro-*p*-oxazine (antipyrilmorpholine)

is best prepared by placing aminoantipyrine, ethylene oxide, and a little water in a sealed tube, which is heated to 60° C. after two days. The mixture is then heated with 50 per cent. sulphuric acid under pressure for several hours at 125°—135° C. The base is taken up with ether from which it separates in rosettes of long colourless needles, m. pt. 157° C. The methiodide melts at 134° C., and is decomposed by warm water. The *bis*-antipyril-piperazine and the antipyrilpiperidine were examined as to their antipyretic action. The toxic dose of both is about the same as that of antipyrine; the antipyrilpiperidine is active in smaller doses than antipyrine. F. S.

Benzaldehyde; [Gravimetric] Determination of small quantities of —. H. Hérissay. XXIII., page 139.

Carbonic Acid; Electrolytic reduction of —. R. Ehrenfeld. XI A., page 126.

Oil of Peru Balsam. U.S. Customs Decision, Dec. 6, 1905.

An oil prepared by distilling balsam Peru is dutiable at 25 per cent. *ad valorem* as an "essential oil" under paragraph 3 of the tariff. The claim of the importer that it was dutiable at $\frac{1}{2}$ cent per lb. and 10 per cent. *ad valorem* as a "drug advanced in value" was overruled. —R. W. M.

Benzyl Acetate. U.S. Customs Decision, Dec. 8, 1905.

BENZYL acetate is dutiable at 25 per cent. *ad valorem* as a "chemical compound" under paragraph 3 of the tariff, as it is not mentioned by name in paragraph 554 which enumerates the coal tar products which are free of duty. —R. W. M.

Mercuric Oxycyanide. K. Holdermann. Arch. Pharm., 1905, 243, 600—617.

It is not possible to prepare pure mercuric oxycyanide by simply heating freshly precipitated yellow mercuric oxide with a solution of mercuric cyanide in the theoretical molecular proportions, since, under these conditions, much less than the requisite amount of the oxide is dissolved. By heating together various proportions of the two substances in different states of dilution, varying yields of mercuric oxycyanide were separated by fractional crystallisation. Only one oxycyanide exists, which has the formula HgO.Hg(CN)_2 . The amount of oxide in an oxycyanide may be readily determined by direct titration, in the presence of sodium chloride, with $\text{N}/10$ hydrochloric acid and methyl orange as indicator. Commercial mercuric oxycyanide contains, without exception, but little of the basic compound. It is doubtful if the pure oxycyanide has the powerful antiseptic properties attributed to it, since the therapeutic experiments on which its reputation is founded, were made with the impure commercial salt, consisting mainly of mercuric cyanide. —J. O. B.

ENGLISH PATENTS.

Thiosinamine; Concentrated solutions of —. E. Merck, Darmstadt, Germany. Eng. Pat. 22,533, Nov. 3, 1905. Under Int. Conv., Dec. 12, 1904.

It is a solution of thiosinamine and sodium salicylate in water or alcohol or the like is evaporated, a white crystalline powder is produced, which is very easily soluble, even in cold water. —F. S.

Antimony Lactate; Double Salts of —. G. B. Ellis, London. From Chem. Fabrik. von Heyden Akt.-Ges., Radebeul, Germany. Eng. Pat. 21,751, Oct. 25, 1905.

ANTIMONY sulphate reacts with a solution of sodium lactate forming antimony lactate. On evaporation the sodium sulphate separates out first, leaving antimony-

sodium lactate in solution. Other metals giving a soluble sulphate can be used in place of sodium; in the presence of sodium salts antimony sulphate reacts with calcium lactate, producing a crystalline soluble antimony-sodium-calcium-lactate. —F. S.

Carbon Tetrachloride; Process and Apparatus for Purifying —. E. F. Côté. Fr. Pat. 357,781, Sept. 15, 1905.

CARBON tetrachloride (freed from carbon bisulphide by a preliminary distillation) and steam are introduced at the bottom of a vertical column filled with a hot solution of sodium or potassium carbonate; this is kept at a temperature above the boiling point of the tetrachloride, so that the latter passes up the column in a state of vapour, whereby it is thoroughly washed, and the sulphur chloride decomposed by the alkali carbonate. The vapours passing out of the top of the column, stated to consist only of pure tetrachloride and steam, are passed through a condenser into a suitable receiver, where they are separated. A detailed description of suitable apparatus for the above process is given. —T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(Continued from page 90.)

Latent [Photographic] Image; Nature of the —. J. M. Eder. Z. wiss. Phot., 1905, 3, 329—353. Chem. Centr., 1906, 1, 210—211.

ACCORDING to the author the substance of the normal latent image on silver bromide (negative of the first order) consists of particles of silver bromide reduced to different degrees and hence containing silver subbromide. On exposing a photographic plate to the light, the first effect is the splitting off of bromine and the formation of a silver subbromide, which is closely related to normal silver bromide, but is reduced to metallic silver by reducing agents, more rapidly than the latter; this form of subbromide is decomposed by sodium thiosulphate and by nitric acid. On continued exposure, a subbromide is formed, which represents the substance of the latent image of an ordinary negative;

this subbromide is attacked only slightly by nitric acid, but is less soluble than silver bromide in solutions of fixing agents such as ammonia, ammonium bromide and sodium thiosulphate, and hence, after the primary fixing process, is left as a residual image capable of physical development. This subbromide, however, is not entirely unaffected by the fixing process; according to the chemical nature, concentration and temperature of the fixing solution, it is decomposed, to a more or less considerable extent, into silver bromide (dissolved by the fixing solution) and metallic silver, so that the final residue consists of subbromide mixed with more or less metallic silver. If potassium cyanide be used as fixing agent, the decomposition of the subbromide is complete, and metallic silver alone is left. If the primary, fixed latent image be acted upon by nitric acid, any metallic silver present is dissolved, and the residual image consists wholly of subbromide capable of physical development. By prolonged action of concentrated nitric acid, however, the subbromide is decomposed into silver bromide and silver (dissolved by the acid), and the image eventually will consist only of normal silver bromide, which, in absence of light, cannot be developed by physical means, but on exposure to light is again converted into subbromide and rendered capable of development.

The substance of the solarisation image produced by strong over-exposure of a bromide plate is not identical with that of the directly visible blackened silver bromide which usually accompanies it, and is also different from the substance of the latent image of a normal negative. The negatives of the second order, produced by strong over-exposure and subsequent development, are probably composed of a mixture of three chemically different substances, namely, metallic silver, the substance of the solarisation image, and the subbromides which form the negatives of the first order. These three substances can be distinguished not only by their behaviour towards photographic developers, but also by the action of sodium thiosulphate, ammonia, nitric acid, &c., on them.—A. S.

Photographs on Silk: Production of —. F. J. Farrell. J. Soc. Dyers and Col., 1906, 22, 24—28.

By immersing silk fibres in cold, dilute nitrous acid, diazonium compounds are produced, which, like those obtainable on wool (this J., 1897, 405—7), are sensitive to light, being thereby rendered incapable of combination with aromatic hydroxy or amino compounds. The above fact may be utilised for producing photographs on silk, as follows:—The silk is washed and immersed in a solution containing 0.5 per cent. of sodium nitrite and 1 per cent. of sulphuric or hydrochloric acid for about six hours; it is now rinsed, dried under tension, exposed beneath a positive for 20–30 seconds in sunlight, and developed in a solution containing 0.5 per cent. each of a hydroxy compound and sodium or potassium hydroxide, at 25°–30° C.; after development, the silk is washed, and immersed in dilute acetic acid and dried. The shades obtained were: with β -naphthol, scarlet; α -naphthol, bluish-red; resorcinol, golden orange; these may be modified by treatment with certain metallic salts: for example, the resorcinol colour is changed by cobalt salts into red violet. The silk diazo compounds will also combine with aromatic amino compounds at about 100° C.; α -naphthylamine, for example, produces an orange; this is a true azo compound, not a diazoamino compound, since the dyestuff can be diazotised and further "developed"; a blue shade, for example, being produced by combination with aminonaphtholdisulphonic acid H(1.8.3.6). The silk diazo compound does not change at once, on exposure to light, to a compound incapable of combination, but is converted into a pink (probably nitroso) compound, which gives a permanent brown colour with alkali hydroxides. Photographs may be obtained, thus, by exposing diazotised silk for a very short time under a negative, and treatment with alkali hydroxide; or the silk may be given a longer exposure under a positive, and then exposed for a short time to light, whereby the "shadows" are converted into the nitroso compound, and are developed by alkali. The azo colours obtained by the above process are very fast to light, and to boiling water.—T. F. B.

Gelatin spontaneously rendered insoluble in darkness: Composition of Bichromated —. A. L. Lumière and A. Seyewetz. XIV., page 129.

Flash-Light Powder. U.S. Customs Decision, Oct. 31, 1906.

A PREPARATION consisting of powdered metallic magnesium and cerium nitrate in separate containers designed to produce flashes of light for photographers, was dutiable at 25 per cent., *ad valorem*, as a "chemical compound" under paragraph 3 of the tariff.—R. W. M.

ENGLISH PATENTS.

Photographic Dry Plates, Films, or the like. W. Fraser, C. Kelly, and J. A. Bentham, London. Eng. Pat. 20,066, Nov. 30, 1904.

PHOTOGRAPHIC dry plates, films or other vehicles are prepared, containing all the necessary developing agents, so that they are developed by immersion in water only. For example, the back of the plate or film is coated with the necessary substances made into a paste with a soluble colloid: the following quantities are given:—Metol, 2 grains; quinol, 4 grains; potassium metasilphite, 0.5 to 1 grain; borax, 10 to 20 grains; and sufficient colloid and glycerin to form the paste.—T. F. B.

Explosives in pieces of large size and of any shape; Process for the manufacture of — from compressed Trinitrotoluene. C. E. Bichel. Fr. Pat. 357,925, Sept. 21, 1905.

EXPLOSIVES for shells, mines and torpedoes are prepared from compressed trinitrotoluene by first forming small pieces of any desired shape and afterwards uniting these small pieces by means of fused trinitrotoluene.—A. S.

XXIII.—ANALYTICAL CHEMISTRY.

(Continued from page 85.)

APPARATUS, ETC.

Mercury Pump; Rotating —. W. Gaede. Physik. Zeits., 1905, 6, 758—760. Chem. Centr., 1906, 1, 1.

THE pump is shown in section in Figs. 1 and 2. It consists of a cast iron cylinder *c*, closed by a thick glass plate *g*,

Fig. 1.

Fig. 2.

and partly filled with mercury. Inside this cylinder is a rotatable porcelain drum A, mounted on the spindle a, (Fig. 1) and provided with concentric and radial division-walls z, m, which divide it into several compartments, K_1 , K_2 . The vessel to be exhausted is connected to the pump at R, and the air is pumped out as far as possible, by means of a water-pump connected to the apparatus at x. The porcelain drum is then set in motion, when the mercury seals off spaces in the porcelain drum, the volumes of which continually alter. The space, K_1 , the volume of which becomes larger, communicates through f_1 with R, whilst the space K_2 which becomes smaller, communicates through A (see Fig. 2) only with the water-pump, which removes the gas forced out. It is stated that with the porcelain drum rotating at a speed of 20 revolutions per minute, a space of 6½ litres volume is exhausted in 20 minutes from 9 mm. pressure to "0.0001 c.c."—A. S.

Distillation in High Vacua; Application of Dewar's method of air-absorption to —, and a shortened form of McLeod gauge. A. Wohl and M. S. Losanitsch. Ber., 1905, 38, 4140–4154.

The authors utilise animal charcoal cooled by liquid air to complete the exhaustion carried so far by a water-pump. The figure shows the apparatus they use when the vacuum-pressure has to be measured.

The apparatus to be exhausted is connected with the vessel V, and the cocks v and w being opened, is exhausted by the water-pump to, say, 20 mm. A, containing 20–30 grms. of animal charcoal, is either connected with the pump during this operation (in which case the exhaustion must not be so rapid as to disturb the animal charcoal) or is connected after closing w and cooling, by slowly opening a. After exhaustion, w is closed, and the liquid air contained in the Dewar vessels, D, D₂, is brought up around A and V. In a few minutes, the pressure is reduced to 0.0001 mm.; and even if the apparatus be not

OP = 14–17 cm, PQ = 4–5 cm, QR = 60 cm.

perfectly tight, the vacuum is kept up for a considerable time by the charcoal. The same charcoal will serve for several successive exhaustions, and, when its capacity is exhausted, it is restored by simply allowing its temperature to rise to the ordinary temperature, when the absorbed air is given off. If the vacuum need not be measured, the apparatus can obviously be greatly simplified.

The modified McLeod gauge is shown in the figure. The gauge M and the cylinder B are in one piece; B can be connected with the pump by the cock b and the rubber tube, and is completely filled with mercury. To make a measurement, cock e is opened, and then b (furnished with a filed channel in the key, see this J., 1902, 1413) very gradually opened, when the pressure of the atmosphere drives the mercury up into M and compresses the gas into the capillary c. By closing e, and setting the water-pump in action, the mercury is brought back again, the cock b being closed as soon as the connection between M and R is clear. The mercury thus never comes in contact with rubber. The vessel T contains phosphorus pentoxide, and the cock m is always kept closed save during a measurement, so as to lessen the possibility of moisture finding its way into the gauge. —J. T. D.

FRENCH PATENT.

Gas; Apparatus for analysing —. Allgemeine Feuer-technische Ges.m.b.H. Fr. Pat. 357,426, Sept. 1, 1905. Under Int. Conv., Sept. 2, 1904.

The apparatus is adapted for the automatic analysis of gas, and is shown in the accompanying figure. The pipe a, with the short tube i, is a by-pass from the main stream of gas; h is a mercury seal, communicating on the one hand with the tube k, which dips into an appropriate absorbent solution in the vessel l, and on the other with the sample-measuring vessel g; b, c, d, e, f and g, constitute a hydraulic pump, by means of which a definite volume of the gas to be analysed is drawn into g and subsequently driven over into the absorbent liquid; m is a tube which projects into g and has a liquid seal n; the tube o extends downwards into the wider tube g, which is open at the top; and the three-way cock p establishes communication

between the vessel *l* and either the burette *t* or the pressure recorder *s*. The apparatus works as follows:—When water enters by the tube *b*, it gradually fills *c*, *d*, *f*, *g*, *r* and *q*. At first the excess of gas sample present in *g* is driven out through *m* and *n*, but when the water reaches the lower end of *m* the remainder of the gas (forming a definite, measured volume) can only escape through *h* and *k*, and it is therefore driven forward into the absorbent solution. Before that, the water rising in *q* has sealed the lower end of the tube *o*. According to the proportion of the sample absorbed by the solution in *l*, more or less pressure is set up in *l*, and is indicated by the recorder *s*, which thus gives the result of the analysis; or the volume remaining unabsorbed may be measured by means of the burette *t*. As soon as the inflowing water reaches its highest point in the siphon tube *c*, the latter overflows and empties the apparatus. As the water flows out of *g*, a fresh sample is drawn in at *i*, the seal at *n* preventing any access of air; and when the water in *q* falls below the end of the tube *o*, the excess of unabsorbed gas in *l* escapes, the pressure in *l* falling to that of the atmosphere. The above described series of operations is then repeated in performing a new analysis.—H. B.

INORGANIC—QUANTITATIVE.

Iron; Determination of —, in the presence of Zinc.
V. Komar. Chem.-Zeit., 1905, 30, 31–32.

The mixed salts of zinc and iron are converted into sulphates, and these dissolved in the least possible quantity of cold sulphuric acid, containing 400 c.c. of the monohydrate per litre. The solution is completely oxidised by nitric acid, and is then evaporated, first over a water bath, and finally to dryness on a sand bath, an acid ferric salt, $\text{FeH}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$ being formed during this process. The dry substance is transferred to a crucible, and heated to constant weight over a burner. After 30–45 minutes the contents of the crucible are treated with water, which dissolves the unchanged zinc sulphate, leaving all the iron as ferric oxide.—F. Spix.

Lead (in Lead Acetate); Volumetric Determination of — as Iodate. L. Moer. Chem.-Zeit., 1905, 30, 9.

This process described is based on the formation of lead

iodate when a soluble lead salt is treated with an excess of potassium iodate. The precipitate obtained is practically insoluble in water, difficultly soluble in nitric acid, but readily soluble in hydrochloric acid with evolution of chlorine. As most of the other heavy metals also give insoluble iodates, the application of the method is limited, but it is useful for the valuation of commercial lead acetate (sugar of lead). One grm. of the latter is placed in a 200 c.c. flask, dissolved in water, a drop of acetic acid being added if necessary, about 70 c.c. of N/10 potassium iodate solution are added and the volume made up to the mark. After mixing and allowing the precipitate to settle, 50 c.c. of the clear supernatant liquid are withdrawn by means of a pipette and mixed with potassium iodide solution. The small quantity of iodine set free by the free acid present in the sample is titrated with N/10 thiosulphate solution. Sulphuric acid is now added and the main quantity of iodine titrated.—W. P. S.

Arsenic; Determination of traces of — by the Marsh-Berzelius Method, and the "Insensitiveness" of Zinc.
A. C. Chapman and H. D. Law. Analyst, 1905, 31, 3–16.

In the Marsh-Berzelius method of determining arsenic, the addition of certain metallic salts to the flask containing "sensitive" zinc, has the effect of preventing the reduction of the arsenic to its hydride; thus salts of palladium, platinum, nickel and cobalt exhibit this "retentive" action, whilst those of cadmium, tin, and lead, and also aluminium, magnesium and the alkali metals, have no such effect. In a similar way, it was found that alloys of most metals with "sensitive" zinc were not capable of reducing arsenious oxide; the alloys of zinc with tin and cadmium are exceptions. If, however, 2 grms. of cadmium sulphate, or stannous chloride, or lead acetate be added to the test flask containing one of these insensitive alloys, the whole of the arsenic is evolved as hydride; an exception to this are nickel-zinc alloys, but in this case a certain amount of the nickel becomes separated from the zinc during solution, and particles of it are deposited on the cadmium surface. It was further found that the addition of 2 grms. of cadmium sulphate rendered "insensitive" zinc capable of reducing arsenic compounds; also that the addition of a cadmium, zinc, or lead salt rendered magnesium sensitive. When using the electrolytic method for determining arsenic, it was found that arsenite solutions were completely reduced in presence of sulphuric acid, when a cathode of lead, tin, or cadmium was used; with other cathodes, a large proportion of the arsenic was retained in the cell; this applies equally to iron cathodes, which have been previously credited with having no such retentive action; when arsenate solutions were reduced electrolytically, similar results were obtained, although in no case was all the arsenic evolved as hydride. It was found experimentally that the addition of any metal which causes insensitiveness had the effect of lowering the potential of the hydrogen formed. The above results show that all metals known to possess low supersaturation values prevent the reduction of arsenious oxide by zinc, whilst others (e.g., cadmium, tin, zinc) which possess high values have no appreciable effect.

—T. F. B.

Sodium and Potassium Cyanide; Determination of soluble Sulphides in Commercial —. G. W. Williams. J. Chem. Metall. and Min. Soc., S. Africa, 1905, 6, 170.

Two portions of 5 grms. each of the sample to be tested are dissolved in 100 c.c. of previously boiled distilled water. To one portion about 0.5 grm. of lead carbonate is added, the liquid well shaken for a few minutes and filtered, the filtrate forming a check solution, free from sulphides, but otherwise, especially with regard to incidental impurities, similar to the actual sample to be tested. 50 c.c. of each solution are then placed in Nessler tubes, and 1 c.c. of alkaline plumbate, prepared by digesting litharge in 5 per cent. sodium hydroxide solution, is added. A solution of sodium sulphide containing 1 mgrm. per c.c. is added to the check solution from a burette until the colour in the two tubes is matched. The colour is then fixed, and immediately attains its maximum intensity.

Sulphides; Conditions of precipitation and solution of Metallic. — G. Bruni and M. Padua. Atti R. Accad. dei Lincei Roma, 1905, 14, [2], 525–528. Chem. Centr., 1906, 1, 215–216.

In 1894 Ostwald stated that by treatment with sulphuretted hydrogen under pressure, it should be possible to precipitate, for example, zinc from acid solutions, and, inversely, if the hydrogen sulphide exert only a very small pressure, lead sulphide and antimony sulphide should be soluble in acids. The authors have experimentally tested these statements. Concentrated sulphate solutions of iron, manganese, zinc and cadmium, and chloride solutions of cobalt and nickel were treated, in presence of hydrochloric acid, with hydrogen sulphide under strong pressure. For this purpose the solution under examination was introduced into a cooled tube containing some liquefied hydrogen sulphide, and the tube sealed. On allowing to stand, the temperature of the tube gradually rose; at the ordinary temperature, the pressure inside the tube amounted to 14.34–16.38 atmospheres. All the solutions gave abundant precipitates of sulphide, except that of manganese sulphate, thus confirming Ostwald, who gave manganese sulphide as the most soluble sulphide in its group. On opening the tubes, contrary to expectation, none of the precipitated sulphides redissolved; even on heating, only the sulphide of zinc went into solution. With respect to the second part of Ostwald's statement, it was found that an acid solution of cadmium sulphate, which under ordinary conditions yielded a precipitate of cadmium sulphide, gave no precipitate with hydrogen sulphide under diminished pressure. — A. S.

Chromium in Steel; Determination of —, by means of Ammonium Persulphate. H. E. Walters. J. Amer. Chem. Soc., 1905, 27, 1550–1553.

The author uses a method by which chromium and manganese can both be determined. It is not directly applicable to tungsten- or molybdenum-steels, which often contain a chromium carbide insoluble in sulphuric acid. If, after solution of the steel, this carbide be filtered off, fused with sodium carbonate, and the product added to the main solution, the process can then be proceeded with. The method is as follows:—The sample, 1–25 grms., is weighed into a No. 3 beaker, dissolved in 35 c.c. of 1:5 sulphuric acid, and a little ammonium persulphate added to the hot solution to oxidise iron and carbonaceous matter; the solution is diluted to 100 c.c., 40 c.c. of silver nitrate solution (0.4 per cent.) and 5–7 grms. of ammonium persulphate are added, and the whole boiled till excess of persulphate is destroyed, say, for five minutes. The solution is transferred to a 500 c.c. flask, cooled, made up to volume, 100 c.c. poured into a 100 c.c. flask, and the remaining 400 c.c. treated in a beaker with a known volume of ferrous sulphate solution of known strength, and titrated with permanganate. The ferrous sulphate oxidised by the sample represents the manganese and chromium in 1 grm. of steel. The smaller portion of 100 c.c. is now titrated in a porcelain dish with sodium arsenite solution till the colour is bright yellow. From this the amount of manganese is calculated, and the chromium is then obtained by difference. — J. T. D.

Sulphur in Zinciferous Residues; Determination of —. G. Lunge and R. Stöcklin. Z. angew. Chem., 1906, 19, 21–27.

Watson's method (this J., 1888, 305), as modified by Lunge, gives results far below the truth in burnt ores

containing zinc, or in those which, even though free from zinc, contain high percentages of sulphur. In such cases the authors find that the addition of chlorate, which Watson proposed to dispense with, is necessary. For burnt ores with less than 5 per cent. of sulphur, their method is as follows:—2 grms. of sodium bicarbonate of ascertained alkalinity are accurately weighed into a nickel crucible of 20–30 c.c. capacity, and thoroughly mixed with 3.206 grms. of the finely-powdered sample and about 2 grms. of potassium chlorate, by means of a flat-headed glass rod. The crucible is heated for 30 minutes by a flame 3–4 cm. high, the tip of which is 2–3 cm. below the bottom of the crucible, 20 minutes with the flame raised so as just to touch the bottom, and 10 minutes with a larger flame which will raise the bottom of the crucible to just visible redness, but not melt the contents. The crucible must be covered, and no attempt made to stir the contents. The crucible is emptied and washed out into a porcelain dish, and the contents boiled with 25 c.c. of concentrated neutral solution of sodium chloride till solid salt begins to separate. The mass is now filtered through a Schleicher and Schüll's 590 filter, and washed with water containing sodium chloride till free from alkalinity. The filtrate is then titrated with N/1 or N/5 hydrochloric acid and methyl orange. From the difference between the amount required and that required by 2 grms. of the bicarbonate used, the percentage of sulphur is calculated. This method answers not only for burnt zinciferous pyrites, but also for burnt blends. When the zinc content is high, the liquid is sometimes slightly turbid from zinc oxide or carbonate; it is best then to carry all the titrations to distinct red.

If the sulphur content be above 6 per cent. the proportions used should be—1.603 grms. of sample, 2 grms. of bicarbonate, 4 grms. of chlorate, and 2–3 grms. of sulphur-free ferric oxide, which keeps the mass porous. Raw blends can also be treated in the same way, using 0.3206 grms. of blonde, 2 grms. of bicarbonate, 2 grms. of chlorate, and 2 grms. of ferric oxide; and the same proportions, omitting the ferric oxide, give a quick and fairly accurate sulphur assay of raw pyrites. — J. T. D.

Rotating Anode and Mercury Cathode; Use of —, in Electro-Analysis. L. C. Kollock and E. F. Smith. J. Amer. Chem. Soc., 1905, 27, 1527–1549.

The arrangements formerly described (this J., 1905, 1127) have been applied to the electrolytic deposition of other metals. Some of the results, and the essential data, are given in the table below, to compare with that formerly given (*loc. cit.*). The experiments with silver, mercury and bismuth showed that nitrates can be used, or nitric acid added to the solution, without affecting the accuracy of the process. An attempt was made to use metallic halides, and at the same time to determine the halogen by using a silver anode. It was found, however, that the coating of silver halide could not be obtained sufficiently adherent, but that portions dropped into the cathode basin. By reverting to the platinum anode, however, and floating toluene or xylene on the liquid, it was found that the electrolysis of halides could be successfully carried out without injury to the anode, the toluene completely absorbing the halogen formed.

The authors have also found that in this way perfect separations of iron can be effected from uranium, aluminium, thorium, lanthanum, praseodymium and neodymium, cerium and zirconium.

Metal.	Weight of metal present	Sulphuric acid or nitric acid present (or toluene).	Volume of electrolyte	Current.	E.M.F.	Speed of anode.	Time.	Weight of metal found.

Antimony; Rapid Deposition of —, by Electrolysis.
J. Laugness and E. F. Smith. J. Amer. Chem. Soc., 1905, 27, 1524—1527.

The authors have repeated Exner's experiments (this J., 1903, 1150), and endeavoured to give the conditions more precise, and thus secure uniformity in the results. The antimony solution (10 c.c., containing about 0.25 gm. of antimony) was placed in the platinum basin used as anode, and to it were added 15 c.c. of sodium sulphide solution (sp. gr. 1.18), 3 grms. of potassium cyanide, 1 c.c. of 10 per cent. sodium hydroxide solution, and water to make up 70 c.c. The solution was heated nearly to boiling and electrolysed with a current of 6 amperes per sq. dem., at 3.5—4.0 volts, with rotating anode, and in 15 minutes the whole of the antimony was deposited as a bright gray adherent coating (results, 0.2402 to 0.2410 gm. instead of 0.2406). With roughened dishes 1 gm. could be accurately deposited in 20—25 minutes.

Two analyses of stibnite were made, 0.5 gm. of the mineral being dissolved in 20 c.c. of sodium sulphide solution, filtered and washed from the insoluble matter, and the solution electrolysed under the above conditions (7 amp., 3 volts, 20—25 minutes). The two results were 71.09 and 70.72 per cent.

The same process affords a means of completely separating arsenic from antimony. Solutions containing 0.1268 gm. of antimony and 0.2000 gm. of arsenic gave in six experiments deposits of antimony weighing from 0.1267 to 0.1269 gm.—J. T. D.

ORGANIC—QUANTITATIVE.

Carbon Bisulphide in Benzene; Determination of —.
D. Stavorinn. J. Gasbeleucht., 1906, 49, 8.

The author applies Peterson's method (this J., 1903, 1017) based upon the formation of xanthogenate from carbon bisulphide and quantitative oxidation of its sulphur with hydrogen peroxide in alkaline solution, to the determination of the small quantities of carbon bisulphide present as impurities in commercial benzene. 25 c.c. of benzene are mixed in a beaker with 70 c.c. of 96 per cent. alcohol and 10 c.c. of 8 per cent. sodium hydroxide solution added. After standing for half-an-hour, 5 c.c. of concentrated hydrogen peroxide solution free from acid are added, and the alcohol is distilled off on the water-bath. The solution is diluted with 200 c.c. of water, acidified with hydrochloric acid, and the sulphuric acid formed precipitated with barium chloride. The method may be adapted to volumetric working by using N/1 sodium hydroxide solution for the xanthogenate reaction and titrating back with N/5-acid using methyl orange as an indicator after oxidation with hydrogen peroxide; 1 c.c. of N/1 sodium hydroxide solution = 0.049 gm. of carbon bisulphide. Thiophene is not attacked by an alkaline hydrogen peroxide solution.—R. L.

Paraffin Scale; Determination of the Oil in —. L. Neustadt. Chem.-Zeit., 1906, 30, 38.

ADVANTAGE is taken of the fact that the oil is completely soluble in acetone, whilst only a small proportion of the wax is dissolved, and this can be entirely removed by cooling the solution to -15°C . One gm. of the finely powdered scale is digested with 10 c.c. of acetone at the ordinary temperature for one or two hours. The mixture is then placed in a freezing bath and cooled to -15°C . The solution is filtered through cotton wool in a filter tube surrounded by a freezing mixture, and the insoluble scale is washed with cooled acetone. The filtrate is collected, the acetone is distilled off, and the oil is dried at 100°C . and weighed. This method gives results which agree perfectly among themselves, but which are always higher than those obtained by the old method of pressing the oil out of the scale mechanically, since the removal of oil in the latter case is never complete.—J. F. B.

Rubber; New method of analysis of Raw —. R. Diltmar. Gummi-Zeit., 1906, 20, 364—366.

To determine moisture, 1 gm. of the raw rubber is dried at 80°C . For the ash, 1 gm. of the masticated rubber is

incinerated in a platinum crucible. For resins, 4 grms. of the masticated rubber are extracted with acetone in a Soxhlet apparatus, whilst for total impurities, 1 gm. of the rubber, after extraction of the resin, is dissolved in 100 c.c. of benzene on the water-bath, and the solution is centrifuged. By subtracting from the weight of insoluble matter that of the inorganic impurities (ash), the percentage of organic impurities (albuminoids, sugars, albanes, &c.) is obtained. The pure rubber is either estimated by difference, or the benzene is distilled off from the clarified solution and the residue weighed.

The following results were obtained in the case of five different rubbers, viz., (1) Guatemala, sandy, from *Castilloa elastica*; (2) Mozambique, unripe, from *Landolphia*; (3) Pará, fine, from *Hevea brasiliensis*; (4) fine, large Mozambique balls, from *Landolphia*; (5) Gambla balls, from *Landolphia Scnegulensis* :—

No.	Moisture.	Inorganic impurities.	Resins.	Organic impurities.	Pure rubber.
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
1	3.155	35.40	9.91	23.26	28.275
2	5.15	14.91	7.04	39.81	33.09
3	3.88	0.31	1.49	0.06	94.26
4	2.47	0.62	11.51	3.0	82.4
5	2.39	40.59	3.48	2.78	50.78

—E. W. L.

Starch; Polarimetric Determination of —. E. Ewers. Z. öffentl. Chem., 1905, 11, 407. Chem.-Zeit., 1906, 29, Rep., 382.

By continued treatment with glacial acetic acid, dilute hydrochloric acid and hot water, starch may be readily and completely dissolved. The author states that this method of dissolving starch is well suited to the quantitative estimation of starch in commercial starches and flours, the amount of starch present in the solution being determined polarimetrically.—T. H. P.

Starch and Amylocelluloses; Determination of Coagulated —. J. Wolff. Ann. Rev. Chim. anal., 1905, through Woch. f. Brau., 1906, 23, 31.

EQUAL quantities of starch are placed with water in three flasks of equal capacity, they are then gelatinised, heated under pressure, and allowed to cool. To flask *a*, 20.5 c.c. of a filtered 10 per cent. infusion of malt are added, and the mixture is maintained at a constant temperature of 60°C . To flask *b* only 0.5 c.c. of the same malt infusion is added; flask *c* receives the same. The contents of flasks *b* and *c* are allowed to remain for three hours at the ordinary temperature until coagulation has taken place. The contents of flask *b* are then diluted to 200 c.c. after the addition of 20 c.c. of the same malt infusion which has been boiled. The contents of flask *c* are then fully saccharified after treatment with 20 c.c. of the unboiled malt infusion, and are also diluted to 200 c.c. The contents of flask *a* are also fully saccharified and are likewise diluted to 200 c.c. All the liquids are filtered and 100 c.c. of each filtrate are heated in the autoclave at 120°C . for 20 minutes. The solutions are neutralised, made up to equal volumes and the dextrose is determined in each, the results being calculated as starch. The difference between *a* and *b* gives the weight of the coagulum; the difference between *a* and *c* gives the weight of the amylocellulose.—J. F. B.

Benzaldehyde; [Gravimetric] Determination of small quantities of —. H. Hérissay. J. Pharm. Chim., 1906, 23, 60—65.

BENZALDEHYDE is precipitated as its phenylhydrazone, formed according to the reaction

The reagent employed, consists of 1 c.c. of freshly redistilled phenylhydrazine and 0.5 c.c. of glacial acetic acid dissolved in 100 c.c. of distilled water.

Fifty c.c. of an aqueous solution of benzaldehyde of the same volume of distillate, obtained after the hydro-

lysis of a glucoside, such as amygdalin, sambunigrin, or prulaursin, with a ferment, is mixed with 50 c.c. of the above reagent, heated on the water-bath for 20 to 30 minutes, and set aside for 12 hours. The precipitate is then collected in a Gooch crucible, washed with 20 c.c. of cold water, and dried to constant weight over sulphuric acid *in vacuo*. The weight of phenylhydrazono obtained $\times 0.54081$, gives the equivalent of benzaldehyde.

Experiments conducted with the hydrolysis of anhydrous amygdalin by means of emulgin, and subsequent distillation of the benzaldehyde formed, have given results in the determination of the latter, which, although slightly below theoretical requirements, indicate the practical value of the method. —J. O. B.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

(Continued from page 93.)

Radium; Effect of high temperatures on the rate of decay of the active deposit from —. H. L. Bronson. Phil. Mag., 1906, 11, 143—153.

CURIE and DAME (Compt. rend., 1904, 138, 748) concluded from the results of experiments on the exposure of the active deposit from radium to high temperatures, that the "rate of decay" of the active material was permanently altered, and that as the temperature to which the deposit was exposed, was raised, the "period" (i.e., the time in minutes required for the activity to fall to half its original value) reached a minimum at about 1100° C., and then began to increase again. The author, however, by heating a copper wire coated with the active substance, in a sealed tube, finds that temperatures between 700° and 1100° C. do not permanently affect the rate of decay of the active deposit from radium, Curie and Danc's results being apparently due to neglect of taking into account the volatilisation of one or more of the constituents of the active deposit. —A. S.

Quartz; Adsorption of Water vapour and of certain Salts in aqueous solutions by —. L. F. Briggs. J. of Phys. Chem., 1905, 9, 617—640. Chem. Centr., 1906, 1, 215.

THE powdered quartz used in the experiments was composed of particles of from 0.005 to 0.25 mm. diam.; 100 grms. were shaken with 150 c.c. of the solution at 22° C. Alkali hydroxides were adsorbed to a much greater extent than alkali carbonates; the amount of adsorption increased with the concentration of the solution. From a N/10-solution of potassium hydroxide, 2.3×10^{-5} gm.-equivalents were adsorbed by 80 grms. of quartz sand with a total surface of about 14,000 sq. cm.; with the powdered quartz, the adsorption was much greater. Neutral salts were not adsorbed to any appreciable extent. Experiments on the adsorption of water vapour, e.g., from dilute sulphuric acid, by powdered quartz, were also made. —A. S.

Solid Solutions. F. Wallerant, Comptes rend., 1906, 142, 100—101.

MIXTURES of isomorphous crystals have sometimes been likened to solutions of one solid substance in another, since their physical properties vary with their composition. The author's results tend to strengthen this view, since they show that both diffusion and re-crystallisation can take place in these solid mixtures. If a mixture of potassium nitrate and ammonium nitrate, containing 80—93 per cent. of the latter salt, be fused and then allowed to solidify, there is obtained, above 104° C., a conglomerate of two kinds of crystals, one being isomorphous with potassium nitrate and containing 80 per cent. of the ammonium salt, the other being quadratio and containing 93 per cent. of ammonium nitrate. At 104° C. the mass becomes cloudy, the crystals can no longer be discerned, and movements take place within the mixture. As a result of this diffusion, uniform zones of crystals are gradually formed, which crystals belong to the monoclinic system, and have a composition intermediate between that of the two components. The converse phenomenon takes place in the case of a mixture of two parts of ammonium

nitrate and one part of cesium nitrate, mixed by fusion and allowed to solidify. The mass first solidifies in the form of cubic crystals, which on further cooling change into rhombohedral crystals isomorphous with those of cesium nitrate. These latter are slowly transformed into a conglomerate of two kinds of crystals, quadratio and rhombohedral, both of which are mixed crystals of the two nitrates of different compositions. —J. F. B.

Prizes.

Alcohol; Prizes for denatured —. Chem. & Drug., Feb. 10, 1906.

The Commission appointed by the French Government to inquire into the methods of examining and methylating alcohol have decided to offer the following prizes for open competition, irrespective of the nationality of the competitors: (1) A prize of 20,000 fr. for a method of methylating alcohol which shall be preferable to that now in vogue in France, and at the same time prevent any defrauding of the revenue; and (2) a prize of 50,000 fr. for a method which shall permit of the use of alcohol for illuminating purposes under the same conditions as those applying to petroleum. Further details may be obtained from the Commission.

Trade Report.

BRITISH CHEMICAL TRADE IN 1905.

The following are further details of the British Chemical trade in 1905. (See this J., 1906, 94):—

New Books.

A HANDBOOK FOR CANE-SUGAR MANUFACTURERS AND THEIR CHEMISTS. By GUILFORD L. SPENCER, D.Sc., Formerly Chief of Sugar Laboratory, U.S. Department of Agriculture, &c. Fourth Edition. Rewritten and Enlarged. First Thousand John Wiley and Sons, New York. Chapman and Hall, Ltd., London. 1906. Price \$3.00.

SMALL 16mo volume, bound in morocco and gilt, containing 320 pages of subject matter with 52 illustrations, and the alphabetical index, followed by list of tables and formulae. The subject is divided into two parts. I. THE MANUFACTURE OF CANE SUGAR, AND II. SUGAR ANALYSIS. The sub-divisions of these branches are as follows:—I. (i) Extraction of the Juice. (ii) Its Purification. (iii) Filtration of the Juice and Scums. (iv) Chemical Reagents used in Purifying the Juice. (v) Evaporation of the Juice. (vi) Preservation of the Juice and Syrup. (vii) Crystallisation of the Sugar. (viii) Curing the Sugars. Disposal of Low-grade Sugar. II. (i) Composition of the Sugar-cane and Molasses. (ii) Properties of the Sugars in the Cane. (iii) Optical and Chemical Methods of Sugar Analysis. (iv) Density Determinations. (v) General Analytical Work. (vi) Chemical Control of Sugar-house Work. (vii) Examination of Bone-black. (viii) Analysis of Limestone, Lime, and Sulphur. (ix) Lubricating Oils. (x) Analysis of Fluogases. (xi) Quality of the Water-supply and Treatment of Impure Water. (xii) Fermentation. (xiii) Special Reagents. (xiv) Reference Tables.

CHAPTERS ON PAPER MAKING. Vol. II. Comprising Answers to Questions on Paper Making set by the Examiners to the City and Guilds of London Institute. By CLAYTON BEADLE. H. H. C. Grattan, 17, The Borough, London Bridge, London, S.E. 1906. Price 5s. nett. (See this J., 1904, 565, for notice of Vol. I.)

SMALL 8vo volume, containing 168 pages of subject matter and the alphabetical index. The work is divided into thirteen chapters, as follows:—I. Technical Education as Applied to Paper-making. II. The Use of Specially prepared Size in Dry Sheets for Paper Sizing. III. to VII. Questions set at the City and Guilds of London Institute's Examination for 1901, 1902, 1903, 1904, and 1905. VIII. Answers to 1901, Ordinary Grade. IX. Answers to 1901, Honours Grade. X. Answers to 1902, Ordinary Grade. XI. Answers to 1902, Honours Grade. XII. Answers to 1903, Ordinary Grade. XIII. Answers to 1903, Honours Grade.

ANREGUNG ZUM STUDIUM DER AUF CAPILLARITÄTS- UND ADSORPTIONSERSCHEINUNGEN BERUHENDE CAPILLAR-ANALYSE. Von FRIEDRICH GOPPELBERGER. Helling and Lichtenhahn's Verlag, vorm. Reich-Deitloff, Basel. 1906.

8vo volume, containing 239 pages of subject matter. The subject is treated under the following divisions or heads: I. History and General Significance of Capillarity. II. Introduction to "Capillary Analysis." III. Capillary- and Absorptive-Behaviour of the Dye-stuffs, Alkaloids, Oils and Naphthas. IV. Application of Capillary Analysis in Inorganic Chemistry. V. Application of Capillary Analysis in the Testing of Foodstuffs, &c., as also in Pharmaceutical Chemistry. VI. Application also in Physiology.

EINFÜHRUNG IN DIE THERMODYNAMIK AUF ENERGIE-TISCHER GRUNDLAGE. von Dr. JULIUS MEYER. Privatdozent an der Universität Breslau. Wilhelm Knapp's Verlag. Halle a. S. 1906. Price M.8.

8vo volume, containing 209 pages of subject matter, and alphabetical indexes of authors and subjects. The entire subject is treated under the following heads: INTRODUCTION. I. Mathematical Introduction. II. and III. Energy and its two Prime Factors. A, IV. Calorimetry. V. Thermometry. VI. Equations of Condition. VII. Thermodynamic Co-efficients. B, VIII. First Principle of Thermodynamics. IX. Employment of Ideal Gases. X. Thermochemistry. XI. Dependence of the Internal Energy on the Temperature. C, XII. Carnot's Process. XIII. The Second Principle of Thermodynamics. XIV. Irreversible Processes. XV. Entropy. XVI. Entropy of Ideal Gases and Gaseous Mixtures. XVII. Applications of the Entropic Theory. XVIII. Absolute Temperature. XIX. Thermodynamic Potentials. XX. Conditions of Equilibrium. XXI. Theory of Phases. D, XXII. Free Energy. XXIII. Application of Isothermal Processes. XXIV. Dilute Solutions. XXV. Law of Mass Action. XXVI. Applications. XXVII. Electrical Energy. XXVIII. Free Energy of Formation. XXIX. Heat of Reaction and the Isochore.

THE LABORATORY BOOK OF DAIRY ANALYSIS. By H. DROOP RICHMOND, F.I.C. Chas. Griffin and Co., Ltd., Exeter Street, Strand, London. 1905. Price 2s. 6d. nett.

SMALL 8vo volume, containing 86 pages of subject matter and the alphabetical index. The text contains 38 illustrations, and is sub-divided as follows:—I. Introduction, Constituents of Milk, and its Products, &c. II. Analysis of Milk. III. Analysis of Liquid Milk-Products. IV. Application of Analysis to the Solution of Problems. V. Analysis of Butter. VI. Analysis of Cheese.

FABRICATION DES PRODUITS CHIMIQUES PROPRIÉTÉ DITS. Royaume de Belgique, Ministère de l'Industrie et du Travail. J. Lebequt et Cie., Rue de la Madeleine, 48, Brussels. Price, 4 fr. 50. post free.

ROYAL 8vo volume, containing 353 pages of subject matter, a classified table of contents, and a frontispiece representing the chemical manufactory at Baelen-Wozel. The work gives a description of the various chemical industries of Belgium; its scope may be judged from the following extracts from the index:—*First Part. Sulphuric Acid and Superphosphates.* I. Mineral Acids and By-products. (1) Sulphuric Acid. (2) Nitric Acid. (3) Sodium Sulphate and Hydrochloric Acid. II. Calcium Phosphates. (1) Superphosphates. (2) Dissolved Guano. (3) Basic Phosphates. III. Accessory Products: Copper Precipitate, Copper Sulphate, Copper Nitrate, Ferrous Sulphate, Ferric Chloride, Barium Salts, Sodium Silicofluoride, Arsenic, Nickel and Copper Arsenides. *Second Part.*

Soda, Chlorides and Potash Salts. I. Sodium Carbonate and By-products. II. Bleaching Powder and Caustic Soda. III. (1) Soda Crystals. (2) Sulphurous Acid and Bisulphites. (3) Magnesium Sulphate, Sodium Hypochlorite, Zinc Chloride, Sodium Sulphide. IV. (1) Potassium Carbonate and Caustic Potash. (2) Potassium and Ammonium Nitrates. (3) Refined Salt. *Third Part. Other Products of Natural Minerals.* I. (1) Alumina and Aluminium Sulphate. (2) Potash Alum. (3) Various Aluminium Salts. II. (1) Phosphoric Acid. (2) Double Superphosphates. (3) Alkali Phosphates. (4) Phosphorus and Copper Phosphide. III. Mineral Colours. (1) Cerussite, Massicot and Minium. (2) Zinc White, Grey Oxide, and Zinc Powder. (3) Lithopone. (4) Ultramarine. (5) Ferric Oxide Pigments. (6) Various Colours. IV. Compressed Gases. (1) Oxygen and Hydro-

gen. (2) Sulphur Dioxide. (3) Carbon Dioxide. (4) Anhydrous Ammonia. V. (1) Sulphur. (2) Barium Sulphate. (3) Borax and Boric Acid. (4) Sodium and Potassium Silicates. *Fourth Part. Coal and Wood Products:* I. By-products of Coal-tar Distillation. II. Secondary Coal-tar Products, Ferrocyanides and Thiocyanates, Ammonia, Ammonium Sulphate, Tar Oils and their Products, Pitch. III. Direct Wood Products. A (1) Tannic Extracts. (2) Salicin. B. Pyroligneous Acid. IV. Secondary Wood Products. (1) Methyl Alcohol and its Derivatives. (2) Calcium Acetate and Products derived therefrom. (3) Wood Tar derivatives. V. Various Organic Products. (1) Ethyl Ether and Acetic Ester. (2) Nitrocellulose and Colloion. (3) Acetaldehyde and Paraldehyde. VI. Fine Chemicals. (1) Laboratory Products. (2) Pharmaceutical Preparations.

JOURNAL OF THE Society of Chemical Industry.

No. 4.—Vol. XXV.

SUPPLEMENT.

February 28, 1906.

HON. TREASURER:—
Samuel Hall, East London Soap
Works, Bow, E.

PRESIDENT:—
Dr. Edward Divers, F.R.S.
GENERAL SECRETARY:—
Charles G. Cresswell.

EDITOR:—
Watson Smith, 34, Upper Park Road
Haverstock Hill, N.W.

OFFICES:—
Telegraphic Address: "59 Palatable, London." 59, Palace Chambers, Westminster, S.W.

Telephone No.: "Victoria," 715.

Journal and Patent Literature.

Class	Page.
I.—General Plant, Apparatus and Machinery	166
II.—Fuel, Gas, and Light	168
III.—Destructive Distillation, Tar Products, Petroleum, and Mineral Waxes	171
IV.—Colouring Matters and Dyestuffs	172
V.—Preparing, Bleaching, Dyeing, Printing and Finishing Textiles, Yarns, and Fibres	176
VI.—Colouring Wood, Paper, Leather, &c.	179
VII.—Acids, Alkalies, and Salts, and Non- Metallic Elements	179
VIII.—Glass, Pottery, and Enamels	181
IX.—Building Materials, Clays, Mortars, and Cements	181
X.—Metallurgy	182
XI.—Electro-Chemistry and Electro-Metallurgy	185
XII.—Fatty Oils, Fats, Waxes, and Soap	188

Class	Page.
XIII.—Pigments and Paints; Resins, Varnishes, &c.; India-Rubber, &c.	188
XIV.—Tanning; Leather; Glue, Size, Bone, and Horn; Ivory and Substitutes	189
XV.—Manures, &c.	190
XVI.—Sugar, Starch, Gum, &c.	190
XVII.—Brewing, Wines, Spirits, &c.	191
XVIII.—Foods; Sanitation; Water Purification; and Disinfectants	194
XIX.—Paper, Pasteboard, Cellulose, Celluloid, &c.	195
XX.—Fine Chemicals, Alkaloids, Essential Oils, and Extracts	196
XXI.—Photographic Materials and Processes	197
XXII.—Explosives, Matches, &c.	198
XXIII.—Analytical Chemistry	199
XXIV.—Scientific and Technical Notes	202

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Bellin et Cie, 55, Rue des Francs-Bourgeois, Paris (3^e).

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Members are reminded that the subscription of 25s. for 1906, payable on January 1st, should be sent at once to the Hon. Treasurer (Mr. Samuel Hall) in order to ensure continuity in the receipt of the Society's Journal.

DECENNIAL INDEX, 1896-1905.

A Collective Index to the first fourteen volumes of the Journal (1882-1895), a volume of 550 pages, was published in 1899: a few copies of this are still left, price 10s. A second volume, embracing the period 1896-1905, is now in preparation, and will be ready for printing in 1906. It will contain both a subject matter and authors' names portion, and will be a volume of about 900 pages, uniform in size with the Journal. As the number of copies to be printed will depend on the number of applications from members, the Treasurer is prepared to receive subscriptions at the rate of 10s. each copy. A form of application for this purpose will shortly be issued.

INDEX FOR 1905.

The Index for 1905 is in the press and is expected to be ready for issue with the March 15th number to those members entitled to receive it.

LONDON SECTION.

The next meeting of the London Section will be held at the Chemical Society's Rooms, Burlington House, Piccadilly, on Monday, March 5th, 1906, at 8 p.m., when Dr. W. D. Borland will read a paper on "The Ignition of Nitro-compound Explosives in Small Arm Cartridges."

On April 2nd, Mr. E. J. Watkins will read a paper on "The Ropiness in Flour and Bread, and its detection and prevention."

MANCHESTER SECTION.

The next meeting of the Section will be held at the Grand Hotel, on Friday, March 2nd, at 7.30 p.m., when Mr. Horbert Porter will read a paper entitled, "Beetroot Sugar Industry in England," the subject being treated under the following heads:—Reasons why it should now succeed. History of its development. Value of sugar-beet for sugar, cattle feeding, and manure. Its cultivation. The sugar factory and sugar extraction.

NEWCASTLE SECTION.

The Annual Dinner of the Section will be held at Tilley's Restaurant, Blackett Street, Newcastle, on March 7th, at 7 p.m. The President of the Society, Dr. E. Divers, F.R.S., has accepted the invitation of the Section for the occasion.

LIST OF MEMBERS AND JOURNAL ABBREVIATIONS.

The List of Members for 1906, with which is included a list of Journals abstracted, with the abbreviations of their titles and addresses where they may be obtained, is issued with this number of the Journal to every member of the Society.

List of Members Elected.

February 22nd, 1906.

Alcock, Frank H., 9, Broad Street Corner, Birmingham, Analyst.
 Appleby, L. C. B., c/o Messrs. R. Bishop & Sons, Newark-on-Trent, Maltster.
 Bauer, H. F., c/o Edwardsburg Starch Company, Cardinal, Ontario, Canada, Chemist.
 Benson, Richard W., Public Analyst's Laboratory, 67, Surrey Street, Sheffield, Analytical Chemist.
 Brooks, Cecil J., 20, Gt. Ormond Street, London, W.C., Metallurgist.
 Clark, Wm. B., 42, Robertson Street, Greenock, N.B., Chemist.
 Coffman, Herbert, 233, South Albany Street, Ithaca, N.Y., U.S.A., Chemist (Portland Cement).
 Cooper, Wm., Public Analyst's Laboratory, 67, Surrey Street, Sheffield, Analytical Chemist.
 Craven, John L., 15, Hutchinson Street, Winthrop, Mass., U.S.A., Chemist and Salesman.
 Davis, V. P., Naugatuck, Conn., U.S.A., Chemist.
 Dobson, S., 22, Dangan Road, Cambridge Park, Wanstead, N.E., Paint Works Manager.
 Dushman, Saul, School of Practical Science, Toronto, Canada, Electro-Chemist.
 Friend, G. Clausen, c/o The D.B. Martin Co., Claremont, Baltimore, Md., U.S.A., Chemist.
 Fuchs, Herman C., 83, Marlborough Road, Brooklyn, N.Y., U.S.A., Dry Colour Chemist.
 Gaunt, Percy, Norman Road, Rusholme, Manchester, Chemist.
 Gerkenmeyer, H. H., 109, South Eastern Avenue, Joliet, Ill., U.S.A., Chemist.
 Gorrie, David, c/o D. Gorrie & Son, South Methven Street, Perth, N.B., Engineer.
 Green, Ernest, 113, Hulton Street, Moss Side, Manchester, Science Teacher.
 Hanfeld, Fred C., 5, West 95th Street, New York City, U.S.A., Wall Paper Manufacturer.
 Haskell, Walter F., 234, Bridge Street, Westbrook, Maine, U.S.A., Textile Chemist and Colourist.
 Herty, Prof. Chas. H., University of North Carolina, Chapel Hill, N.C., U.S.A., Professor of Chemistry.
 Hoyer, Fritz, 49, Market Street, Perth Amboy, N.J., U.S.A., Chemist.
 Ingalls, Robert C., 53, Commercial Street, West Lynn, Mass., U.S.A., Sales Manager, Fine Chemicals.
 Kirby, Oswald F., The Leeds Institute, Leeds, Lecturer on Chemistry.
 Knapp, Walter R., c/o Sémec-Solvay Co., Ensley, Ala., U.S.A., Chemist.
 Macdougald, G. D., City Laboratory, 13, Shore Terrace, Dundee, City Analyst.
 McDowell, Alex. H., c/o General Chemical Co., Bayonne, N.J., U.S.A., Chemist.
 McGregor, Russell, Public Analyst's Laboratory, 67, Surrey Street, Sheffield, Analytical Chemist.
 Mason, Frederic S., 54, Rue Rennequin, Paris, France, Manufacturing Chemist.
 Mason, Corradino, Castelguelfo Parmense, Parma, Italy, Sulphuric Acid and Manure Maker.
 Mills, W. H., Northern Polytechnic Institute, Holloway, London, N., Lecturer on Chemistry.
 Murphy, Fred W., Standard Sugar Refinery, Granite Street, South Boston, Mass., U.S.A., Chemist.
 Myles, C. D., 16, St. Loo Mansions, Cheyne Gardens, London, S.W.
 Nathan, Albert, c/o Warfield & Duell, 220, Broadway, New York City, U.S.A., Patent Lawyer.

Nestell, Raymond J., 115, West 68th Street, New York City, U.S.A., Instructor in Analytical Chemistry.
 O'Brien, John W., c/o Grasselli Chemical Co., Grasselli, Lake Co., Ind., U.S.A., Acid Manufacturer.
 Ogilvie, Alex. M., 7, Millbrae Crescent, Langside, Glasgow.
 Parke, Jas., School of Practical Science, Toronto, Canada, Chemist.
 Rossi, A. J., c/o Roesaler & Hasselacher Chem. Co., Perth Amboy, N.J., U.S.A., Mining Engineer.
 Rossi, L. M., Perth Amboy Chem. Works, Perth Amboy, N.J., U.S.A., Mining Engineer.
 Schneible, Joseph, 14th Floor, Rector Building, Chicago, Ill., U.S.A., Chemical Engineer.
 Schroeder, C. M. E., 221, Pearl Street, New York City, U.S.A., Analytical Chemist.
 Scott, Arthur P., c/o Dominion Iron and Steel Co., Sydney, Cape Breton, Canada, Chemist.
 Seiter, F. J., 3401, Charlton Street, Chicago, Ill., U.S.A., Chemist.
 Small, Frank E., Foyle Villa, Merton Road, Bootle, Liverpool, Works Chemist.
 Smith, Arthur D., 91, Avenue C, Bayonne, N.J., U.S.A., Chemist.
 Smith, Arthur G., Washington Portland Cement Co. Baker, Wash., U.S.A., Chief Chemist.
 Smith, Robert C., 425, Home Avenue, Oak Park, Ill., U.S.A., Chemical Engineer.
 Stickland, Oliver W., c/o The New Explosives Co., Ltd., Stowmarket, Suffolk, Works Chemist.
 Strans, Louis, 18, West 83rd Street, New York City, U.S.A., Merchant.
 Symes, Langford P., Parcora Freezing Works, Timaru, N.Z., Chemist.
 Tempson, H. A., Government Laboratory, St. John's, Antigua, West Indies, Analyst.
 Tolman, Frank S., 451, State Street, Flushing, N.Y., U.S.A., Superintendent (Oakes Manufacturing Co.).
 Warwick, Philip H., c/o Messrs. J. Richardson & Son, Millgate, Newark-on-Trent, Maltster.
 Webb, Frank H., P.O. Box 104, Apponang, R.I., U.S.A., Chemist.
 Weiss, Philip, jun., Wharton Furnaces, Wharton, N.J., U.S.A., Chemist.
 Wheeler, Frank G., Trenton, Mich., U.S.A., Chemist.
 Wilke, Wm., 86, Norwood Avenue, Buffalo, N.Y., U.S.A., Chemical Engineer.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Allen, Charles A., 1/o Irlams; 188, Harwood Street, Darwen, Lancashire.
 Baron, W. Briscoe, 1/o Manchester; c/o Jos. Crosfield & Sons, Ltd., Warrington.
 Bartripp, G. F.; all communications to 51, Pulteney Road, South Woodford.
 Bielecki, Dr. Jan, 1/o Marzalkowska; 66, Krakowski Przedmiescie, Warsaw.
 Bond, Josiah, 1/o Somerville; Patagonia, Arizona, U.S.A.
 Braman, W. W.; all communications to Box 353, State College, Pa., U.S.A.
 Bruce, Jas., 1/o Belfast; Craik, Saskatchewan, Canada.
 Buchanan, E. F., 1/o Akron; Nürnhergerstrasse 3, Berlin, W., Germany.
 Burnside, C. F., 1/o Parlin; California Powder Works, Santa Cruz, Cal., U.S.A.
 Carter, Stewart F.; Journals to Park Place, Suffern, N.Y., U.S.A., Superintending Chemist.
 Charlton, Thos., 1/o San Francisco; 325, Irvington Place, Denver, Colo., U.S.A.
 Chilwell, John, 1/o Wednesbury; Post Office, Auckland, New Zealand.

Collingridge, Frank, 1/o Beaufort Road; 73, Fountain Road, Edghaston.
 Crighton, W. H., 1/o Newington Green; 33, Ardleigh Road, Southgate Road, London, N.
 Davis, Charles B.; all communications to o/o National Brewers' Academy, 402, West 23rd Street, New York City, U.S.A.
 Davis, Emerson, 1/o Cass Avenue; 30, Watson Street, Detroit, Mich., U.S.A.
 De Blois, W. H., 1/o Pulaski; c/o General Chemical Co., Hudson Heights, N.J., U.S.A.
 Edgerley, D. W., 1/o New York; c/o The Chilton Paint Co., 120, High Street, Boston, Mass., U.S.A.
 Fudge, Thos., 1/o 397; 604, Avenue E., Bayonne, N.J., U.S.A.
 Goodchild, W. H., 1/o Borneo; Elmwood Lodge, Long Lane, Finchley, N.
 Hammersley, W. S., 1/o Longjumeau; 15, Rue des Carriers, Soignies, Belgium.
 Hasting, J. J., 1/o Water Street; c/o Louis Leavitt, North 11th Street and Driggs Avenue, Brooklyn, N.Y., U.S.A.
 Humphrey, R. L., 1/o Philadelphia; U.S. Geological Survey, Exposition Grounds, St. Louis, Mo., U.S.A.
 Johnson, Edw., 1/o Rua do Comercio; c/o Herdeiros Bowman, Ltd., Caixa 57, Pernambuco, Brazil.
 Johnson, F. M. G.; communications to University College, London, W.C.; Journals as before.
 Krause, Dr. G.; Journals to Verlag der Chemiker Zeitung, o/o Otto von Halem, Cöthen, Anhalt, Germany.
 Lane, Fred H., 1/o Park Place; 418, Sackett Street, Brooklyn, N.Y., U.S.A.
 Le Maistre, F. J., 1/o Philadelphia; Eastern Laboratory, Chester, Pa., U.S.A., Research Chemist.
 Levy, Arthur G., 1/o Maida Vale; 45, Clifton Hill, Abbey Road, London, N.W.
 Main, Wm., 1/o Brooklyn; Piermont, N.Y., U.S.A., Chemist.
 Mardick, Jno. R., 1/o Du Bois; Westminster, Md., U.S.A.
 Masujima, Prof. B., 1/o 19; 23, Midoricho-Itchome, Honjoku, Tokyo, Japan.
 Maxim, Hudson, 1/o Sterling Place; 698, St. Mark's Avenue, Brooklyn, N.Y., U.S.A.
 Mellen, E. D., 1/o Curtis, Davis & Co.; President (Pilot Range Mining Co.); Journals to Cambridge, Mass., as before.
 Mercer, C. A.; all communications to 34, Camomile Street, London, E.C.
 Milroy, Andrew; all communications to 48, Dunmont Road, Shawlands, Glasgow.
 Morris, Harry, 1/o Avenue House; The Hall, Hexthorpe, Doncaster.
 Munton, Fred. T., 1/o Runcorn; The Oak House, Winsford, Cheshire.
 Neave, Geo. B., 1/o George Street; Technical College, Montrose Street, Glasgow.
 Neech, Herbert R.; 1/o Huelya; St. Catherine's, Lincoln.
 Paine, Augustus G., 1/o Times Building; 41, Park Row, New York City, U.S.A.
 Palmenburg, O. W., 1/o West 70th Street; 80, St. Nicholas Avenue, New York City, U.S.A.
 Park, James, 1/o 51; Hillside House, 42, Millburn Street, Glasgow.
 Parker, Charles E., 1/o New Brunswick; 1361, Fairmont Street, Washington, D.C., U.S.A.
 Pettit, Alf., 1/o Glenwood Road; 375, State Street, Brooklyn, N.Y., U.S.A.
 Pierce, Ira L., 1/o Atlantic Manufacturing Co.; o/o Eastern Dynamite Co., Barksdale Plant, Washburn, Wis., U.S.A., Superintendent.
 Saxe, Sigmund, 1/o New York City; Bradford, Pa., U.S.A.
 Sisson, George, jun., 1/o Washington; 13, Grey Street, Newcastle-on-Tyne, Technical Chemist.
 Strayer, D. W.; all communications to o/o Oxford Copper Co., Camden Works, corner State and Tenth Streets, Camden, N.J., U.S.A.
 Swindells, Seth, 1/o Scholar Green; Holly Villas, Lawton, Stoke-on-Trent.
 Tobey, C. R.; Journals to Burks Falls, Ont.; and (subscriptions) Collingwood, Ontario, Canada.
 Furb, C. C., 1/o Syracuse; c/o Solvay Process Co., Detroit, Mich., U.S.A.

Van der Linde, Harold; all communications to 101, Tyndall Avenue, Toronto, Canada.
 Vogel, P. C., 1/o Cass Street; c/o Pfister and Vogel Leather Co. (Journals) Milwaukee, Wis., U.S.A., and (subscriptions) 18 Market Street, Bermondsey, S.E.
 Walker, Dr. Wm. H.; Journals to Massachusetts Institute of Technology, Boston, Mass., U.S.A.
 Watt, H. E., 1/o Dartford; 228, Ladywood Road, Birmingham.
 Watson, John C.; The Bleachery, Saylesville (not Taylorsville), R.I., U.S.A.
 Whowell, Fred., 1/o Bolton; Croich Hey, Tottington, Bury, Lancashire.
 Woodward, Horace A.; Journals to 1268, Amsterdam Avenue, New York City, U.S.A.
 Zimmele, H. B., 1/o Howe Street; 200, Bellfield Avenue, Pittsburg, Pa., U.S.A.

Deaths.

Bardsley, Robt., Messrs. Jewsbury and Brown, Manchester. Feb. 20.
 Clark, Augustus, Fundicio do Bowman, Pernambuco, Brazil.
 Hurst, G. H., 22, Blackfriars Street, Salford. Feb. 8.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted." Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (1) in the case of Applications for Patents, the dates of Application, and (2) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

- [A.] 2316. Renshaw. Tank wagons for transporting petroleum, naphtha and other liquids. Jan. 30.
 " 2419. Critien. *See under XVIII.*
 " 2535. Soc. C. et G. Grimmeisen. Cooling apparatus. [Fr. Appl., Feb. 3, 1905.]* Feb. 1.
 " 2591. Higginbottom. Washing, rinsing and whizzing granular matter, sugar, ores, minerals, and the like. Feb. 2.
 " 2718. Brook. Furnaces. Feb. 3.
 " 2755. Ruttkamp. Mixing machines.* Feb. 5.
 " 2991. Boulton (Goldman and Co.). Filters.* Feb. 7.
 " 2992. Boulton (Goldman and Co.). Filters.* Feb. 7.
 " 3080. Politz. Furnaces.* Feb. 8.
 " 3135. Kapf. Method of reducing organic or inorganic compounds.* Feb. 8.
 " 3229. Dewrance. Filter presses. Feb. 9.
 " 3240. Stoddart. Manufacture of filtering media from slag. Feb. 9.
 [C.S.] 2097 (1905). Stocker. Drying various substances, such as clay. Feb. 7.
 " 2102 (1905). Stocker. *See under IX.*
 " 2520 (1905). Fieldhouse. Tanks for producing a liquid free from suspended solids. Feb. 14.
 " 5668 (1905). Spooner (Cie. pour la Fabr. des Compteurs et Material d'Usines à Gaz). Apparatus for measuring high temperatures. Feb. 14.
 " 7901 (1905). Lennox and Mackenzie. Means for evaporating liquids and concentrating the solids in the same. Feb. 14.
 " 7962 (1905). Lennox and Mackenzie. Evaporators for evaporating the liquid in brewers' wash, spent wash or pot ale, waste or spent dyes, &c., and concentrating the solids in the same. Feb. 14.
 " 8342 (1905). Lennox and Mackenzie. Evaporators for evaporating the liquid in brewers' wash, spent wash or pot ale, waste or spent dyes and the like. Feb. 7.
 " 19,277 (1905). Spooner (Artificially Separators). Centrifugal separators. Feb. 14.
 " 26,622 (1905). Dickins. Combined measuring glass and pestle and mortar. Feb. 7.

II.—FUEL, GAS, AND LIGHT.

- [A.] 2213. Goodwin. Suction gas producers. Jan. 29.
 " 2245. Hoering and Wielandt. Gasifying raw combustible materials.* Jan. 29.
 " 2250. Simpson. *See under X.*
 " 2368. Tully and Shadbolt. Apparatus for the manufacture of gas. Jan. 30.
 " 2437. Zerning. Manufacture of filaments for incandescent lamps.* Jan. 31.
 " 2440. Hugerhoff. Carburetting apparatus.* Jan. 31.
 " 2498. Milne. Manufacture of gas for illuminating, heating and power purposes. Feb. 1.
 " 2554. Zerning. Manufacture of filaments for electric incandescent lamps.* Feb. 1.
 " 2831. Spieske. Heat storing compound. Feb. 5.
 " 2907. Wilton. Purification of gases produced in the destructive distillation of coal or other carbonaceous substances.* Feb. 6.
 " 2929. Sims and Bowes. *See under VII.*
 " 3003. Stuart-Bailly. Coking coal and ovens therefor. Feb. 7.
 " 3006. Winand. Production of a working medium for internal combustion engines. [Ger. Appl., Feb. 8, 1905.]* Feb. 7.
 " 3060. Griffin. Suction gas producers. Feb. 8.
 " 3089. Jensen (Maemoeke). Thermic mixtures.* Feb. 8.
 " 3145. Streubel. Incandescent mantles. [Ger. Appl., March 24, 1905.]* Feb. 8.
 " 3213. Just, Hanaman, Landesberger, Salzmann, and Verein. Elektrizitäts A.-G. Manufacture of incandescing bodies for electric incandescent lamps. Feb. 9.
 " 3225. Just, Hanaman, Landesberger, Salzmann, and Verein. Elektrizitäts A.-G. Manufacture of incandescing bodies for electric incandescent lamps. Feb. 9.
 " 3339. Clama. Manufacture of oil gas and apparatus therefor. Feb. 10.
 [C.S.] 5008 (1905). Bowman and Southworth. Gas producers. Feb. 7.
 " 10,496 (1905). Lanc. Gas producers. Feb. 14.
 " 18,403 (1905). Siemens und Halske A.-G. Incandescence bodies of tantalum wire for electric glow lamps. Feb. 7.
 " 24,137 (1905). Dürr and Hudler. *See under XXIII.*

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

- [A.] 2289. Wynne. Purifying hydrocarbon oils. Jan. 30.
 " 2316. Renshaw. *See under I.*
 " 2606. Lockwood. Process for incorporating mineral oils with saponaceous or saponified materials. Feb. 2.
 " 2680. Crowley and Payne. Lubricating oil.* Feb. 3.
 " 2907. Wilton. *See under II.*
 " 3192. Wetter (Rud.-Rüttger Chem. Fabrik. f. Theerprodukte). Manufacture of pitch from tar. Feb. 9.
 [C.S.] 11,191 (1905). Braschler-Kurtz. Method of treating bituminous substances, resins, oils, waxes, &c. Feb. 7.
 " 21,518 (1905). Roth. *See under XXIII.*

IV.—COLOURING MATTERS AND DYESTUFFS.

- [A.] 2622. Imray (Meister, Lucius und Brüning). Manufacture of yellow azo dyestuffs. Feb. 2.
 " 2797. Imray (Meister, Lucius und Brüning). Manufacture of pure bordeaux-red sulphurised dyestuffs. Feb. 5.

Official Notices.

EXTRAORDINARY GENERAL MEETING OF THE SOCIETY.

Notice is hereby given that an Extraordinary General Meeting of the Society will be held at 3.30 o'clock, precisely, in the afternoon of Tuesday, the twenty-seventh day of March, 1906, at the House of the Society of Arts, John Street, Adelphi, W.C., by kind permission of the Council of that Society, with the object of considering and adopting the resolution mentioned in the Requisition hereinafter set forth:—

"TO THE PRESIDENT AND COUNCIL OF THE SOCIETY OF CHEMICAL INDUSTRY."

We, the undersigned Members of the Society of Chemical Industry, hereby request that, in accordance with Bye-Law 40, you will convene an Extraordinary General Meeting of the Society with the object of considering, and if approved by the said Extraordinary Meeting, of adopting the following resolution (that is to say):—

RESOLUTION.

"That it is desirable that the Society of Chemical Industry as now existing should be incorporated under and subject to the grant of a Royal Charter and that the Council be and hereby is authorised to take all necessary steps to procure the grant of a Royal Charter of Incorporation."

Dated this twenty-second day of December, 1905.

Here follow signatures of the following:—

George Beilby.	Henry de Mosenthal.
V. G. Bloode.	Prof. Chas. E. Munroe.
Jas. H. Bowman.	Jas. P. Murray.
Eugene A. Byrnes.	Robert W. Neff.
Eustace Carey.	A. L. Norton.
Prof. Frank Clowes.	D. H. T. Peplow.
Frederick P. Dewey.	Dr. W. H. Perkin.
Dr. Edward Divers.	Dr. Frederick B. Power.
Dr. A. R. L. Dohme.	Sir William Ramsay.
Thos. Fairley.	Sir Boverton Redwood.
Dr. Fred. W. Frerichs.	Walter F. Reid.
Oscar Guttman.	President Ira Remsen.
Samuel Hall.	Sir Henry E. Roscoe.
Jas. Otis Handy.	George D. Rosengarten.
Dr. B. J. Harrington.	Dr. Samuel P. Sadler.
Dr. Edward Hart.	Alfred Gordon Salomon.
Otto Hehner.	Dr. Karl F. Stahl.
E. Grant Hooper.	H. E. Stuart.
David Howard.	Sir Joseph W. Swal.
H. Aug. Hunieke.	H. P. Talbot.
C. C. Hutchinson.	M. J. Taylor.
Prof. Edward H. Keiser.	E. C. Thompson.
Prof. W. R. Lang.	Dr. T. E. Thorpe.
Ivan Levinstein.	Prof. W. A. Tilden.
Arthur R. Ling.	Thos. Tyrer.
Anthony McGill.	John H. Usmar.
Edward Mallinokrodt.	W. H. Van Winekel.
N. H. Martin.	S. S. Voorhees.
Prof. R. Meldola.	Dr. W. H. Walker.
Dr. Rudolph Messel.	R. A. Wallace.
Dr. W. Leah Miller.	Charles Wightman.
Dr. Ludwig Mond.	Dr. H. W. Wiley.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome, commencing on April 25th, 1906. All communications should be addressed to the General Secretary, Prof. Vittorio Villavecchia, Via Panisperna, 89, Rome.

The attention of Members is drawn to the Notice which accompanied the February 15th issue of the Journal. The Executive of the Congress have arranged with Messrs. Thos. Cook & Son, of Ludgate Circus, E.C., 54, Piazza Esdra di Termini and 15 Piazza di Spagna, Rome, to procure suitable accommodation for members during the Congress, and a list of hotels has been prepared at which accommodation can be secured.

Cook & Son will also furnish, on application, full information as to train services.

The General Secretary will be obliged if those members, who have made arrangements directly with the Congress Committee in Rome, will forward their names to the Society, in order that arrangements may be made for a headquarters in Rome and for combined travelling. It would also be of service if they would indicate their contemplated date of departure and proposed route, and also whether they have a preference for any particular hotel in Rome.

Deaths.

Bardsley, Robt., Messrs. Jewsbury and Brown, Manchester. Feb. 20.

Clark, Augustus, Fundicio do Bowman, Pernambuco, Brazil.

Hurst, G. H., 22, Blackfriars Street, Salford. Feb. 3.

Canadian Section.

Meeting held at Toronto on Thursday, October 19th, 1905.

DR. F. J. SMALE IN THE CHAIR.

A STUDY IN CRYSTALLISATION.

BY PROF. JAS. H. BOWMAN.

Those engaged in practical crystallisation are frequently confronted with the fact that many influences, some apparently trivial, affect the process. Great concentration or rapid cooling gives small crystals, less dense solutions or slow cooling produces larger ones. Agitation is also a factor to be reckoned with, as it diminishes the size, while quiescence furthers a large growth. Glauber's salt crystals, for instance, may be reduced to the size of those of Epsom salts, or increased to the dimensions of walnuts, according as these conditions are observed. Not only do we have the same substance crystallising in varying sizes, but in differing forms, so that in a large crystallisation it is sometimes difficult to find a typical shape. If this is true of chemically manufactured crystals, how much more does it apply to those produced in nature which engage the attention of the mineralogist? The crystals of the rocks are often distorted, twisted and compounded, in many cases being only partially formed and defective. The same mineral may vary in form as greatly as a cube differs from a fibre.

One is led to think that the force which causes matter to crystallise is either subject to many vagaries, or that the laws which govern it are frequently interfered with. These considerations suggest the desirability of a study of the force directing the tendency to crystallise.

It is common knowledge that the tendency to crystallise varies widely. The colloids do not crystallise; other substances assume the crystal form only under most favourable conditions and then, perhaps, but obscurely; and still others exist only in a crystalline state.

In studying the influences which affect crystallisation, it is necessary to keep this in mind, as it is assumed that the force with which we are dealing is the measure of this tendency to crystallise, so that in those substances which crystallise with difficulty interference would more readily take place than in those which are strong crystallisers.

If, with a fused crystalline substance, there be mixed a colloid, crystallisation will be interfered with. If, with a crystallised substance in solution, there be mixed a soluble colloid, interference with crystallisation will take place in a similar way. This interference will produce one or more of the following results:—

- (a) Total prevention of crystallisation.
- (b) Suppression of some of the lines of crystallising growth.
- (c) Extension of the crystal to abnormal proportions, causing it to become a compound crystal.
- (d) Bleeding, grating, and curving of the crystal cells.

FIG. 1.

Sodium chloride series—showing transition from solid crystal to extended framework; does not polarize.

FIG. 2.

Santonine crystals in colloidal medium.

FIG. 4.

Grass-like crystals of potassium platino-cyanide and gum arabic.

FIG. 3.

Salol series.—From solid crystal to fibres, showing reticulated "relay" crystals grown to many times their normal size, and relay taking place in both principal and subordinate lines of growth. Crystallized from fused salol and balsam.

FIG. 6.

A rounded form of crystal converted into radiating fibres, with some of the fibres showing a secondary growth.

FIG. 5.

Pyromellitic acid and castor oil showing "relay" on both principal and subordinate lines of growth.

In explanation of these results, I offer the following hypotheses:—

(1) That there are lines of force along which crystallisation takes place which differ in intensity according to the shape of the crystal and also to their nature whether principal or subordinate.

(2) That the interference with crystallisation referred to occurs because the supply of material is not available to the growing crystal as quickly as the crystallising force requires it.

Method of investigation.—I selected a number of crystallisable substances having the following characteristics:—

(1) They covered a large range, so far as crystallising tendencies were concerned.

(2) They had strong polarising action on light.

(3) They were readily dissolved or fused.

(4) They were miscible with some colloid and not too easily decomposed.

A small quantity of one of these substances was fused or dissolved on a glass slide, together with a suitable colloid, and allowed to crystallise by cooling or evaporation. This was repeated with varying proportions of the ingredients, thus forming a series.

The first clause of the hypothesis, viz., that there are directing forces in a crystal and that they manifest themselves in lines, of which there are principal ones leading from the centre of growth, and subordinates lateral to them, may be readily shown by crystallising a solution of common salt in gum arabic water, on a glass slide. (See Fig. 1, which is a fair sample of the result which may be obtained from a large number of substances treated in this way.)

The second clause, viz., that crystallisation is interfered with by lack of supply, was demonstrated in these experiments by introducing a colloid with the solvent or fused substances. Fig. 2 is a slide of santonine. The medium with which the santonine was mixed in this case was a colloid, which is solid at ordinary temperatures and is soft, but not liquid, at 100° C., at which temperature the substance was allowed to crystallise. The determined efforts of the santonine to crystallise are here well illustrated in its gyrations and loopings. By increasing the proportion of colloid, crystallisation was completely prevented.

The following principles are operative, under the conditions of the experiments, in the formations of the crystals:—

(1) Initiation; (2) Repression; (3) Relay; (4) Curving.

Initiation.—It is a familiar fact that if a crystal be introduced into a solution of the same substance, crystallisation will be induced. As an illustration, I may instance fused salol, which, when touched with a small salol crystal adhering to a needle point, immediately begins to crystallise. This "initiation" is a very important principle in all stages of the process of crystallisation.

Repression.—When crystallisation is taking place in a liquid, currents are set up, to and from the forming crystals. The rate of the currents is affected by the strength of the crystallising force and, also, by the thickness or viscosity of the liquid. If the supply of material is not brought to the crystal as fast as the crystallising force demands, the growth will follow the principal lines, i.e., the lines of strongest force, and result in the suppression or partial suppression of the subordinate lateral lines, this giving the crystal a tendency to become fibrous or filiform.

Relay.—By this I designate a process by which a compound crystal is formed. It may be described as follows:—The growing point of a crystal pushes itself into new material and becomes the cause of initiation. The advancing crystal is repeatedly relayed by the force of other crystals, and in this way will grow indefinitely, unless prevented, either by obstruction or lack of supply. Not only does relay take place along the principal force lines, but along the subordinate ones as well. When the latter are "relayed" they initiate lines equal, or nearly equal, to the principal lines. (See Figs. 3 and 5.)

Curving.—Where the crystallising force is nearly equalled by the resistance of the medium due to its viscosity, the crystal seeks the line of least resistance,

which seems to be a gyratory one. The result is the twisting and curving of the crystal or its parts into feathery, fern-like or arborescent shapes.

Between the normal crystal and the fibre many stages exhibit themselves, as shown in the illustrations, viz., reticulated, grass-like, fern-like, arborescent, &c. See Figs. 3, 4, 5 and 6. To exhibit these forms there were projected on the screen slides of tartaric acid, antipyrin, potassium quadroxalate, salicylic acid, oxalic acid, pyrogallol, &c. Illustrations of these forms may also be found among minerals, in zinc, on the surface of galvanised iron sheets, and more familiarly still in the frost-work on our windows in winter. The logical inference from these experiments is that all crystals, if treated by some suitable method, may be made to elongate or twist or even become fibrous. I have found this result in so many cases that I think it may prove true of all, save where the crystallising force is so strong that no colloid, equal to the task of restraining it, can be found.

In crystals having one diameter longer than the other, the conversion to the fibrous form is easier than where the diameters are alike. In studying the building of a crystal, the growing edge should be the point of observation. The foregoing demonstrations make this very apparent.

A crystallisation which admirably illustrates my position, and at the same time gives extremely beautiful effects with the projection apparatus, is that of camphor monobromide. The crystal is formed by fusing a small quantity of the salt with some fir balsam on a glass slide, placing over the mixture a cover glass and allowing it to crystallise. It forms a mass of curving, feathery, concentric rainbows of brilliant colours, and, as an exhibition of crystal growth, can hardly be excelled. Heated to about 70° C. it will fuse, and if then placed in the lantern or on the microscope stage, in a few seconds it will begin to crystallise and for some time will give very beautiful and instructive results. By varying the proportion of the salt and the balsam, the principles I have been contending for, may be illustrated. A mica plate improves the exhibit.

MR. EUSTACE CAREY IN THE CHAIR.

HURTER MEMORIAL LECTURE.

THE UNION OF CHLORINE AND HYDROGEN.

BY HAROLD B. DIXON, M.A., F.R.S., late Fellow of Balliol College, Oxford; Professor of Chemistry in the University of Manchester.

That one, who has devoted a large part of his scientific life to the study of the influence exerted by minute traces of matter on chemical reactions, should be invited to give the Hurter Memorial Lecture is, I take it, not only a compliment to me, but a tribute to the catholicity of the man in whose honour we meet here to-night. Those who knew Ferdinand Hurter admired him not only as a man of indomitable energy and remarkable insight, and of wide reputation in the domain of applied chemistry, but also as a man whose soul, soaring above mere results, ever desired to penetrate the mysterious mechanism of chemical change. I make no apology then in asking you to consider, in this lecture dedicated to Hurter's memory, the mode of combination of chlorine with hydrogen, and the extraordinary influence exerted by traces of foreign matter on the reaction, a study interwoven with that so ably worked out by Hurter on the decomposition of hydrogen chloride acid by oxygen.

My own work on chlorine was begun with the object of

testing the law of mass action in gases. I had studied the division of oxygen between hydrogen and carbonic oxide (the original problem attacked by Bunsen), and had found it complicated by the fact that oxygen and carbonic oxide are largely inert towards one another in an explosion. A simpler case seemed to be presented by the division of hydrogen between oxygen and chlorine. In conjunction with my pupil Mr. J. A. Harker, I measured the small contraction which took place when electrolytic hydrogen and chlorine combined in a glass vessel, and found it to be due to the condensation of hydrogen chloride on the surface. Mr. Harker carried out the experiments on the explosion of the three gases, and found that an equilibrium was reached between two opposite chemical changes:

similar to that found for hydrogen, carbonic oxide and oxygen:—

In the next place we were driven to measure the velocity of explosion of electrolytic hydrogen and chlorine. Among the many possible reactions of gases, I think no one would choose those of chlorine as a subject for exact quantitative study, if he could find any other gas that would answer his purpose. In my case, I could find no other gas having the desired properties, viz., that it should explode with another elementary gas, that the product should be nearly a perfect gas, and that no alteration of chemical volume should accompany the change. A mixture such as hydrogen with nitrous oxide gives water-vapour on explosion; a mixture of cyanogen with oxygen in equal volumes gives a product of sufficiently perfect gases (carbonic oxide and nitrogen), but there is an increase from two volumes to three. Now I had been led to develop a theory of the explosion-wave in gases which attributes the propagation of the explosion to the movement of an intense sound-wave through the gases, a wave which is re-inforced and kept uniform from layer to layer by the chemical action accompanying the collisions of the molecules in the wave-front. The theory did not fit with the facts observed when carbon compounds were burnt to carbonic acid, or when hydrogen compounds were burnt to water-vapour at the highest temperatures of the explosion. The explanation appeared* to be the dissociation of the carbon dioxide or water formed in the wave-front, for, on diluting ordinary electrolytic gas with excess of hydrogen or oxygen or nitrogen, the found rates approximated more and more to the rates calculated by the theory. On the other hand, when the chemical volume was altered by the change, the products would be, for the moment, hotter or colder according as the volume was increased or diminished—just as if they had been suddenly compressed or rarified mechanically. In calculating the theoretical rate of the "sound-wave" in the explosion of such gases, I assumed the temperature must be raised or lowered by the adiabatic compression or rarefaction corresponding to the change in volume. But obviously such an assumption required to be confirmed by experiments with mixtures which did not alter in volume. What mixture would give the same volume on explosion, and also a nearly perfect gas as product of the explosion? The only mixture I could think of was that of chlorine with hydrogen, exploding to hydrochloric acid. Accordingly this mixture had to be tried.

The first difficulty was to obtain a tube sufficiently long to measure the explosion-wave in; for the theory indicated that it would travel about 1700 m. per second. A platinum tube 50 m. long, and about 10 mm. in diameter would have answered the purpose. In default of this I tried various base metals, hoping that a coating of chloride once formed might protect the tube from further action. But the tubes had voracious appetites which could not be allayed; the chlorine seemed, like Cleopatra, to make them hungry when most she satisfied. Then I turned to glass. I thought that a long tube might be drawn out and coiled as it was drawn, but my request to manufacturers to make me such a coil met with expressions of derision which left me a little sore. At length I received an invitation from a firm in Manchester to visit their works, where I had the pleasure of seeing such liberties taken with hot glass that I had great hopes they could easily draw me a tube say

—to be modest—60 ft. long. But when I put my hopes into words I was met by the crushing rejoinder:—"You have seen our works; where do you think we have got room to draw a tube 60 ft. long? The thing is impossible!" I retired crest-fallen; but the firm were better than their words. A month afterwards I received a note from them saying "we have drawn you two straight tubes 34 and 31 ft. long, come and take them away." I had not thought about the tubes being straight, and for a moment their transport presented some difficulty. But very early one morning four men might have been seen marching through Manchester with a long ladder on their shoulders. The tubes were loosely tied to the ladder, and by the removal of a window frame, the ladder was introduced into a corridor of the laboratory, where the two tubes were joined together and my dream of a 60 ft. glass tube became in reality one of 65 ft. The apparatus was completed by attaching a short metal tube at either end to carry the silver-bridges, taps, firing wires, &c.—the interior of these tubes being coated with paraffin and filled with hydrogen and oxygen. They were joined on to the glass tube (upon the latter was filled with hydrogen and chlorine) immediately before the gases were fired. A year later it was possible to obtain 6 ft. iron tubes lined with glass, tubes which could be screwed up tight to one another with paraffined asbestos washers. In this way I built up a glass tube 120 ft. long, and confirmed the earlier experiments.

The first point to determine in the explosion of hydrogen with chlorine, was whether aqueous vapour retarded or facilitated the explosion. I knew of no published researches on this point, when our measurements began; most experimenters had used moist gases. But Pringsheim's work (1887) showed that moisture has a great effect on the union of hydrogen with chlorine under the influence of light, and our work confirmed this in a striking way. We found the light required to explode hydrogen and chlorine, when dried by phosphorus pentoxide, was 25 times more intense than that required to explode the moist gases.* I can easily demonstrate to you the effect of drying the gases, by submitting a dry and a wet bulb to the light from a "magnesium flash" equidistant from the two bulbs. The wet bulb is shattered to powder, the dry bulb remains intact. But this is not the case when the gases are fired by an electric spark. The mean velocity of the explosion-wave in dried hydrogen and chlorine is 25 m. per second faster than the mean velocity in the moist gases. In other words, once the explosion-wave is set up by the spark, it appears to travel independently of the moisture present which merely acts as a diluent. The velocity of explosion in electrolytic chlorine and hydrogen was found to be rather less than the velocity calculated by my sound-wave formula, but much nearer to the calculated number than in the case of the explosion of electrolytic oxygen and hydrogen. When a mixture of two volumes of hydrogen with one of chlorine was exploded, the found and calculated velocities were in close agreement. I interpret this to mean that, in the explosion of equal volumes of hydrogen and chlorine, the temperature in the wave-front is high enough to dissociate some hydrogen chloride. In the following table I compare the found and calculated rates of explosion for some very different mixtures of gases:—

Rates of the explosion-wave in metres per second.

Mixture.	Found.	Calculated.
$8\text{H}_2 + \text{O}_2$	3,535	3,554
$\text{H}_2 + 3\text{O}_2$	1,712	1,740
$2\text{H}_2 + \text{Cl}_2$	1,849	1,832
$\text{C}_2\text{H}_2 + \text{O}_2$	2,728	2,725
$\text{C}_2\text{H}_2 + 2\text{O}_2 + 8\text{N}_2$	1,734	1,727

It is almost inconceivable that the rates of explosion for such very different mixtures of gases could be given

* These experiments have been repeated with great care by H. B. Babar and by Mallor and Russell with chlorine and hydrogen prepared in different ways. The thoroughly dried gases not only resist the action of sunlight, but require a much higher temperature to start their combination.

by the formula unless the mode of propagation were similar in each case. I believe, therefore, that chlorine combines directly with hydrogen at the high temperature of the explosion wave.

The first observation on the union of hydrogen and chlorine under the influence of light is due to W. Cruikshank in 1801. Dalton, in the summer of 1809, experimenting with the mixed gases over water, noticed that a diminution did not take place immediately on exposure to light, but only after a minute or two; that the more powerful the light the more rapid is the combination; that the combination is checked by shading the eudiometer; and that bright sunlight causes an explosion. Gay-Lussac independently observed the explosion of the mixed gases in bright light.

The systematic study of the action of light on hydrogen and chlorine was taken up by Draper in 1843. He devised an ingenious U tube for preparing the gases electrolytically, and storing them over water saturated with chlorine in the closed arm of the U. The diminution in volume, owing to the formation of hydrogen chloride and its solution in the water, was read off on a scale attached to the open arm. This instrument he called a tithonometer, and the action of light on the mixture he called tithonisation. The name is a somewhat puzzling one. The only derivation I can think of is from the Greek demi-god Tithonos, the husband of Aurora. Now Tithonos is pictured in Greek mythology as a decrepit old man shrinking before the brilliance of his wife—the goddess of the dawn. Tithonisation would, therefore, be the process by which a man absorbs the penetrating shafts directed upon him by his more brilliant wife, and finally shrinks up when she casts the light of her countenance too continuously upon him. The name may be appropriate for the absorption of light and the subsequent shrinking of hydrogen and chlorine—though we cannot help wondering whether Dr. Draper was a confirmed misogynist. Sir Henry Roscoe, with greater gallantry, has rejected the name in favour of "actinometer."

Armed with his tithonometer Draper proved that a large amount of radiant matter is absorbed before chemical combination takes place, that combination then begins slowly and increases in rapidity until a constant rate is attained. He showed that the change impressed on the chlorine by the absorption of light prior to the combination was not lost on standing in the dark for some hours. Draper also showed that the maximum sensitiveness to light was attained when the gases were present in exactly equal volumes, a small excess of either gas retarding the rate of combination considerably.

Draper established the fact that after the rate of combination had become constant the movement of the tithonometer was proportional to the quantity of the incident rays.

One of the most important observations made by Draper is that chlorine, when exposed to sunlight, and then mixed (in the dark) with hydrogen, combines immediately with the hydrogen when the mixture is exposed to diffused daylight; whereas "non-insolated" chlorine, when mixed with hydrogen in exactly the same way, shows a long period of inactivity. This change in the chlorine produced by sunlight lasts a long time, and is not due to any temporary elevation of temperature. Draper, therefore, regarded the light as being absorbed by the chlorine and as exalting its affinity for hydrogen: insolated chlorine being thus an allotropic form of ordinary chlorine. It has always appeared to me difficult to explain away the fact recorded by Draper; but other observers, working with apparently more delicate instruments, failed to detect any difference between insolated and non-insolated chlorine. It remained for Bevan to explain this discrepancy.

Bunsen and Roscoe greatly improved the apparatus for observing the action of light on the mixed gases, and their actinometer has served as the model for all subsequent instruments used in these investigations. It will be interesting, therefore, for you to examine the actinometer on the table, one of the original instruments devised by Bunsen and Roscoe. I think the chief improvement we have since made in this apparatus is in the electrolytic cell, where we use for the electrodes carbon rods fused into

glass tubes. Working with this actinometer, Bunsen and Roscoe proved conclusively that pure electrolytic chlorine and hydrogen, in equal volumes, when exposed to light, form no hydrochloric acid for the first few moments, but after a time they begin to combine with a gradually increasing rapidity until a permanent constant action is obtained. This "period of induction," as Bunsen and Roscoe called it, was attributed by them to the breaking down by the action of light of a resistance to the combination of the two gases; they did not consider that the chlorine was altered *per se* by the light, or its affinity exalted. In fact, their experiment of bringing the insolated gases by separate tubes into the induction vessel appeared to show that chlorine, when illuminated by itself, was just in the same condition as unilluminated chlorine. This discrepancy, Bevan has shown, is due to the action of the water in the induction vessel. If chlorine is illuminated over water (as in Draper's experiment) and hydrogen is added to it, the mixture is found to be sensitive to light; if the chlorine is illuminated in a tube and then bubbled through water, the "activity" of the chlorine may be destroyed by the water (as in Bunsen and Roscoe's experiment). It still remains to be explained why the water should so act, and on this problem I hope to show you some very recent experiments that throw light on it.

On another important feature of the "Induction" Bunsen and Roscoe's experiments differ from those of Draper. Draper thought that the induced gases retained their sensitiveness indefinitely; Bunsen and Roscoe found that the induction effect gradually died away in the dark, although the diminution of activity in the dark was much slower than the increase in the light. Here, again, an explanation of this gradual diminution of sensitiveness has only recently been attained. Bunsen and Roscoe also showed the great effect on the amount of combination due to the presence of a small excess of either of the gases, hydrogen or chlorine; and the still more marked diminution caused by the presence of small amounts of oxygen. This marked effect of small quantities of the reacting gases shows that the combination in the light is not governed by the ordinary law of mass action.

When the chlorine and hydrogen mixture brought to the sensitive state is illuminated for an instant, e.g., by an electric spark from a Leyden jar, there is a sudden expansion of the gases, followed immediately by a contraction. This effect was described by Draper. Fringsheim, who seems to have rediscovered this "Draper effect" independently, attributes it to the dissociation of the molecules and the recombination of the dissociated atoms. He considered that he had shown that no hydrochloric acid was produced by the momentary illumination, and, therefore, that the expansion could not be a heat effect. Fringsheim was the first to produce evidence that water took part in the reaction between chlorine and hydrogen under the influence of light. His idea was that the steam was decomposed by the chlorine forming an intermediate compound, e.g., an oxide of chlorine, which, in turn, was decomposed by the hydrogen with formation of hydrochloric acid and water:—

The rate of production of hydrochloric acid depends, then, on the amount of hypochlorous oxide present, and this depends on the length of exposure and the intensity of the light. When the rates of formation and decomposition of the hypochlorous oxide have become equal, the formation of hydrochloric acid will continue at a constant rate which will depend upon the intensity of the light.

Among those who have worked in the Owens College during recent years on the union of hydrogen and chlorine Dr. J. W. Mellor has particularly studied the "Draper effect." He has shown, I think conclusively, that the sudden expansion is always accompanied by the formation of hydrochloric acid, and is probably due to the heat evolved in its formation. Mellor has proved that if the intermediate body is formed in the period of induction, it cannot be either hypochlorous oxide or the corresponding acid, hypochlorous acid, for the addition of either of these bodies does not hasten the combination. To account for the period of induction

Mellor assumes that an intermediate "associated" compound is formed by the chlorine, water and hydrogen. Hevan, on the other hand, having shown that moist chlorine is made active by light, as Draper had stated, assumes that an intermediate compound of chlorine and water is first formed, and that this reacts with hydrogen forming hydrochloric acid and water.

Another mode of attacking the problem of the mode of action of light is to determine the filtering effect of chlorine on the actinic rays. Bunsen and Roscoe found that a mixture of chlorine and hydrogen absorbed more light than a mixture of chlorine with an inert gas; and Mellor has found that moist chlorine forms a hotter light-green than dry chlorine. Further experiments on these lines are wanted.

I have now to bring before you a short account of the recent work which has been carried out in the Owens College by Messrs. D. L. Chapman and C. H. Burgess. The details of their experiments and their theoretical conclusions are not yet published, but I am permitted to show you experimentally with one of their actinometers the important fact they have established, viz., that mixtures of hydrogen and chlorine may be made which retain their sensitiveness to light for an indefinite period—mixtures that have in short no period of induction. According to Chapman and Burgess the pure gases always combine instantaneously; it is the presence of impurities in minute traces that produces the period of induction.

In their earlier experiments, Chapman and Burgess proved that the gaseous mixture, rendered active by light, lost its activity on standing over water in the dark, but that this loss became less marked on each repetition of the experiment with the same water. Finally, however, the loss, though slight, *did not entirely disappear*. This led them to suspect that the induction period might be due to some impurity, and that the water might acquire from the glass vessels something that retarded the rate of combination. These experiments clearly established the necessity of making the water "active" as well as the gases themselves. When salt solutions, e.g., calcium or barium chloride were employed instead of water, far longer induction periods were observed. But after sufficient insolation and shaking of the solution with the gases the latter became as sensitive as over water. The substitution of a quartz vessel for the glass actinometer appeared to confirm the view that glass destroyed the activity; but the effect was really due to the fact that the quartz vessel had been heated in order to drive out the air. Experiments at 100° C. soon demonstrated that water and salt solutions heated with chlorine became rapidly "active." The question whether the decay of activity on standing in the dark was increased by raising the temperature was also tested; the rate of decay of thoroughly insulated gas over barium chloride solution was *diminished* by heating. If light produces some "active principle" in chlorine capable of bringing about the combination of hydrogen and chlorine, heat also has the power of producing the same principle in chlorine water, and water saturated with this "activity" no longer dissolves out the active principle from the active gases in contact with it. Moreover, the "activity" cannot be pumped out of the solution with the dissolved chlorine; on the contrary, a solution from which the chlorine had been pumped away was found to be more "active" than the solution saturated with chlorine.

Chapman and Burgess had now shown that solutions of certain salts had the power of stopping the formation of hydrochloric acid for many hours, but that once the induction period was over the gases combined rapidly under the action of light. This was difficult to reconcile with any theory of the gradual formation of an intermediate compound, since such a compound should be formed at the same rate that it is afterwards decomposed when the constant state is reached. Again, Chapman and Burgess introduced into an active mixture of hydrogen and chlorine, standing over an active solution, an equal volume of an uninsolated mixture of the gases. If an intermediate compound were already present in the active gas, one would expect that its effect would be diminished by the dilution, but the formation of hydrochloric acid was absolutely stopped for a considerable period.

The difficulty of reconciling these several results with any theory of the formation of an intermediate compound led Chapman and Burgess to consider another possible explanation. Could the solution contain some impurity which alone or by reacting with chlorine could give off a volatile body capable of stopping the reaction until completely destroyed? Ammonia seemed such a possible impurity, and experiments promptly showed that it possessed the required properties. Solutions rendered "active" by boiling with chlorine were rendered "inactive" by the addition of a trace of ammonia when cold. On exhaustion, the ammonia or its chlorine derivative was removed, and, of course, on boiling the solution with chlorine the ammonia was destroyed. Chapman and Burgess have shown that the induction period is proportional to the quantity of ammonia in the water. They have further shown that the very slow decay of activity, found when the active actinometer is allowed to stand for several days in the dark, is due to the oxidation of some trace of albuminous substance in the water with the formation of ammonia or its derivatives. Water or salt solutions which have been well boiled with chlorine show no "decay."

The actinometer on the table before you was prepared by Mr. Chapman and has now been standing some 28 hours in the dark. I will ask you to observe the position of the index on the scale while I flash on to the bulb the rays from an incandescent electric light. Notice the instantaneous expansion (the Draper effect) followed by the steady movement of the liquid along the scale towards the bulb. There is no period of induction but a uniform formation of hydrochloric acid.*

But if Chapman and Burgess have explained the induction period by their laborious research and close reasoning, we have still to answer the question "How does the water-vapour influence the combination?" If chlorine can act on hydrogen in presence of water, why does it not do so so long as the ammonia-impurity is present? It is conceivable that chlorine slowly forms a compound with water, and that this compound rapidly acts on the ammonia-impurity by chlorination, hydrochloric acid being formed only when all the impurity is destroyed. But to my mind there are great difficulties in this view. The facts established by Chapman and Burgess can, however, be otherwise interpreted. I have not seen their interpretation, but, on thinking over their experiments, several possible solutions presented themselves to me, and one interpretation which I think worthy of your notice was suggested to me by the phenomena—so much under observation at this moment—of a large political meeting. The individuals—the molecules of the meeting—were not reacting under the stress of collisions in a more or less heated state; they—like our hydrogen and chlorine molecules in light—were being acted on from a distant platform by mere vibrations of a sympathetic kind, and were being induced and stirred to future action. Suddenly a young lady waved a banner and lifted up her voice—unsympathetically. If it had been a question of a change brought about by collisions between individual bodies, the young lady would have had very little chance to effect anything among so many more powerful bodies; but her effect on the *harmony* of the meeting was instantaneous and complete. The whole programme of proceedings was stopped for half an hour.

Suppose that the system Cl_2 , H_2O , H_2 is set gradually vibrating by light and that, when the proper harmonic vibration is set up, then it is possible for chemical change to occur. Now the presence of a small quantity of a vibrating body "out of tune" might stop the harmonic vibration of the other molecules, and so stop the chemical action. A very small proportion of the discordant body might suffice.

I told Mr. Chapman my interpretation of his facts when he at once said, "That is the essence of the explanation I have worked out."

* On repeating the experiment after the lecture, a drop or two of the liquid from the scale tube entered the bulb. On drawing the liquid back and re-illuminating the bulb, there was a distinct period of induction lasting 2 or 3 minutes. The trace of impurity in the index liquid was then destroyed, and further experiments showed no induction.

I have in conclusion to invite your inspection of the apparatus which Mr. E. O. Edgar and I have recently used to redetermine the atomic weight of chlorine by combining it directly with hydrogen. When we commenced this work, four years ago, it required some courage to think that any useful purpose could be served by redetermining a constant which the highest living critic declared had been measured with "the magnificent accuracy of Stas' determination." But, by the time our measurements were completed, evidence began to come in indirectly that possibly even Stas might have made a mistake. But apart from any considerable error in any of Stas' determinations, the very indirect method by which the atomic weight of chlorine had been determined made it certain that an error in any part of the chain connecting chlorine with hydrogen would be repeated from link to link, and would become evident only when the two ends of the chain were connected up.

A direct comparison between hydrogen and chlorine might not only serve to detect any systematic error in this chain of ratios, but such a comparison, inasmuch as it does not involve the probable errors of other ratios, would be *ceteris paribus* more exact. Again, the closing of the chain between hydrogen and chlorine with reasonable accuracy would permit the accidental errors to be distributed and prevent their accumulation at the unconnected end. The accumulated probable error in Clarke's recalculated value for chlorine is 0.0048; the probable error of the mean of our nine experiments is 0.0019.

The suggestion to carry out this work was made to us by Professor Edward W. Morley, who happened to visit our laboratories when pure chlorine was being prepared by the electrolysis of fused silver chloride. He suggested that we should burn weighed hydrogen and chlorine in a closed vessel, just as he had burnt weighed hydrogen and oxygen.

Chlorine was prepared for our determination by the electrolysis of silver chloride fused in a Jena glass U-tube, to the arms of which purified carbon poles were fused. The chlorine was condensed to a liquid and weighed in a glass bulb connected with a sealed tube and tap. After the bulb had been weighed and brought into position, the sealed tube was broken by a small glass rod falling on it inside the apparatus. The gas could then escape by the tap and ground tubulure into a large combustion-globe. The tap had the peculiarity that its smaller diameter was at the top, so that instead of the key having to be pushed into its sheath, it had to be pulled into it to fit. The pressure of the chlorine, therefore, instead of tending to loosen the key, only made it fit more tightly. The hydrogen, prepared by the electrolysis of a hot solution of barium hydroxide, was dried by potash, passed over heated spongy platinum to eliminate any oxygen, then through long U-tubes filled with purified phosphorus pentoxide, and was finally absorbed by palladium. After the apparatus had been well washed out with hydrogen, the palladium bulb was sealed off and weighed. The hydrogen was introduced slowly from the palladium into the combustion-globe previously filled with chlorine. A spark lighted the jet which was kept burning by regulating the supply of the two gases until all the chlorine had been volatilised. About 2 per cent. of chlorine remained unburnt in the globe, which contained pure water to absorb the hydrogen chloride as it was formed. The residual gases were then analysed.

The mean of our nine determinations gives the atomic weight of chlorine as 35.195 if $H=1$, or 35.463 if $O=16$. Our value is considerably higher than that given in Prof. F. W. Clarke's "Recalculation of the Atomic Weights," viz., 35.447. But that Stas' figure is too low has been confirmed indirectly by the work of Prof. Theodore Richards on the ratio between silver and chlorine, and by the work of Dr. Scott and of Mr. R. W. Gray on the atomic weight of nitrogen. It may indeed turn out that the highest of the values found in our nine experiments are more nearly correct than the mean. Mr. Edgar is continuing the investigation and hopes to avoid one source of error by burning the chlorine at a jet in an atmosphere of hydrogen.

We have to thank our glass-blower, Mr. Otto Baumbach, for the skill with which he has made this apparatus.

MR. R. J. FRISWELL IN THE CHAIR.

THE LOSS OF NITRE IN THE CHAMBER PROCESS

PART II.

BY J. K. H. INGLIS.

(See also this J., 1904, 643.)

Up till the last few years the methods which have been available for the analysis of a mixture of gases have been those in which the changes in volume of the gases have been measured either when the gases were passed through some liquid which absorbed one of the constituents, or when chemical action between two or more of the constituents was brought about by means of a spark. Now although these methods are quite satisfactory when the percentages of the different constituents are all tolerably large, they are not at all accurate or convenient when the constituents which are to be estimated form only a very small percentage of the whole. Thus, for example, if the percentage of carbon dioxide in the air is to be determined by measuring the contraction that takes place when a given volume of the air is treated with potash, an extremely elaborate and complicated apparatus is necessary in order that the changes in temperature and pressure may be compensated. Hence such a determination is more conveniently carried out by determining the carbon dioxide itself by chemical methods, e.g., by absorbing it in standard baryta and titrating the excess of baryta with oxalic acid. But in a case in which the constituent cannot be absorbed in such a way (e.g., nitrous oxide), the analytical methods have almost completely failed.

The discovery of convenient methods for preparing liquid air at a moderate cost has placed a new method in the hands of the analyst. For many years the chemist has been in the habit of separating liquids from one another by the process of fractional distillation; and since by means of liquid air nearly all gases can be turned into liquids or solids, one has only to devise methods for the convenient fractionation of these solids and liquids in order to produce the desired separation. In the case of the ordinary distillation of liquids the process is usually carried out at constant pressure and the separation of two miscible liquids can be carried out completely only if the line representing the dependence of the boiling point upon the composition of the liquid presents no minimum or maximum. In the case of the distillation of liquefied gases, however, it is more convenient to carry out the distillation isothermally; and although the above limitation still remains valid, yet the conditions of temperature and pressure can be changed so readily that the separation is more likely to be complete.

The methods for the fractionation of liquefied gases were first worked out and used by Ramsay and Travers (Proc. Roy. Soc., 1898, 63, 438; 64, 183; Phil. Trans. 1901) in their work on the new gases of the atmosphere, and the fact that krypton and xenon were discovered although they amount to only one part in several millions by volume, shows what an extremely good separation can be effected by this method. It seemed possible that the same process might be suitable for the solution of some of the difficult problems in gas analysis; and Sir Wm. Ramsay kindly suggested that I should attempt to solve in this way a problem which arises in connection with the chamber process for the manufacture of sulphuric acid. In this manufacture an amount of nitre has to be continually supplied which is equal in weight to about 2 per cent. of the total sulphur burnt. A large number of investigators have attempted at different times to determine what becomes of this nitre, but their efforts have not been very successful. The result has been that manufacturers have not known to what this loss was due, and therefore have not been able to prevent it.

Now, whatever view we take of the theory of the reactions in the chambers, the nitre must be considered as being present either as nitric oxide, nitrogen trioxide, or nitrogen peroxide, and if there is sufficient excess of oxygen the nitre should not be present as nitric oxide for any length of time. Hence, since nitrogen trioxide and peroxide are both soluble in sulphuric acid (C.O.V.) forming nitrosulphonic acid $\text{NO}_2\text{SO}_3\text{H}$ (and possibly nitric acid) they should be retained by the acid which passes down the Gay-Lussac tower. This acid, when it is passed down the Glover tower, is denitrated by the sulphur dioxide coming from the burners, and the reaction may be written as

Hence, since the nitric oxide formed passes on into the chambers, all the nitre should be retained in the plant and theoretically no fresh supply should be needed. When it was found that, in spite of the Gay-Lussac towers, a steady supply of nitre was necessary, two rival theories arose to explain the loss. According to the one theory (Vorster, "Dingler's Journal," 213, 500), which was brought forward as an objection to the use of the Glover tower, there took place in this tower, in addition to the action already given, the following reaction:—

In this way a portion of the nitrous gases was supposed to be reduced to nitrous oxide, and as this is not absorbed by the sulphuric acid in the Gay-Lussac tower, and, in addition, is of no use in the manufacture of sulphuric acid, it would be a total loss. Lunge ("Dingler's Journal," 225, 474) showed, however, that the conditions under which Vorster carried out his experiments never obtained in the Glover tower, and maintained that the loss due to the formation of nitrous oxide could never be very great. The other theory was that the loss took place solely because of incomplete absorption in the Gay-Lussac tower. This incomplete absorption might be due (1) to the nitre remaining as nitric oxide, and therefore being unabsorbed, (2) to insufficient contact between the gases and the sulphuric acid, or (3) to the fact that the nitrous vitriol formed would have a certain dissociation pressure, and that therefore a certain proportion of the nitrous gases would always remain unabsorbed. But since, in the Gay-Lussac tower, the gases come in contact with a stream of sulphuric acid flowing the opposite way, they should, as they leave the tower, be in equilibrium with the acid entering the tower, viz., pure sulphuric acid, and therefore should contain no nitrous gases. For many years a controversy raged between the exponents of the "chemical" loss and those of the "mechanical" loss, and the question has never been satisfactorily settled. There is no doubt that the chemical loss was at first greatly exaggerated, some chemists (this J., 1884, 2, 134; 1880, 8, 167) even saying that the chemical loss could account for 31 per cent. of the nitre lost. But in the same way, Soré ("Traité," pages 313, 393) declared that the unavoidable mechanical loss amounted to 95 per cent. of the whole loss. In all probability the loss was due to both causes.

Since, according to both theories, the nitre was carried away in the flue leading from the Gay-Lussac tower, it might be thought that an analysis of these flue gases would prove which theory was the correct one. But in these flue gases there was a very large proportion of nitrogen and oxygen, and therefore analyses were difficult to carry out. Some nitrogen peroxide and some nitric oxide were certainly present, but it was difficult to absorb them completely. In addition to this, the flue gas usually contained a small quantity of sulphur dioxide, and when the gases were passed through any absorbent a complicated series of side reactions took place between the nitrogen peroxide and the sulphur dioxide, and the result was that the analytical data could not be interpreted. In addition to this, there was no absorbent for nitrous oxide when its partial pressure was so small, and, therefore, its presence could not be detected much less estimated. This problem, therefore, seemed to be one which might be solved by carrying out analyses by means of fractionation at low temperatures.

Since the nitre lost (calculated as sodium nitrate) is

equal in weight to about 3 per cent. of the sulphur burnt, it is possible, if we assume that the whole nitre lost is carried away in the flue gases, to calculate what proportion by volume this loss represents. In the pyrites burners about 48 per cent. of the ore is sulphur which burns to form sulphur dioxide, another 48 per cent. is iron, which burns to form ferric oxide, and the remaining 4 per cent. remains more or less unchanged. Now, 32 grms. of sulphur will require $\frac{1}{2} \times 22.4$ litres of oxygen to form sulphur trioxide, and 56 grms. of iron require $\frac{1}{2} \times 22.4$ litres to form ferric oxide. Hence 100 grms. of ore require

$$\left(\frac{48}{32} \times \frac{3}{2} + \frac{48}{56} \times \frac{3}{4} \right) \times 22.4 \text{ litres of oxygen} = 64.8 \text{ litres.}$$

The flue gases usually contain about 6.5 per cent. of oxygen, which is 5.5 per cent. of the original volume of air. Hence $21 - 5.5 = 15.5$ per cent. of the air passing through the burners is the quantity of oxygen used to form sulphur and iron oxides. Therefore, each 15.5 vols. of oxygen used means 84.5 vols. of flue gas, i.e., 100 grms. of ore mean 353 litres of flue gas.

The loss of nitre corresponding to 100 grms. of ore is 3×48 gm. sodium nitrate which would give a volume of

$$\frac{3 \times 48}{100} \times \frac{22.4}{85} \text{ litres} = .380 \text{ litre} = 380 \text{ c.c.}$$

The nitric oxide = $\frac{3 \times 48}{100} \times \frac{22.4}{85}$ litres = .380 litre = 380 c.c. The loss of nitre should therefore give rather more than 1 c.c. of nitric oxide or an equivalent amount of any other oxide per litre of flue gas.* This calculation shows, therefore, that if a workable quantity of the nitrogen oxides is to be obtained, the volume of gas dealt with must amount to 10–20 litres. Now, although this volume of gas can be easily worked with when once condensed to a liquid, yet it would not be easy to carry gaseous samples of 10–20 litres from the sulphuric acid works to the laboratory. It was, therefore, necessary to carry out the first stages of the fractionation at the works themselves.

The flue gases consist of (1) a mixture of nitrogen and oxygen containing about 6.5 per cent. of the latter. This mixture does not liquefy under atmospheric pressure at the temperature of liquid air boiling in an open vessel ($-189^\circ \text{C}.$); (2) nitric oxide, at $-189^\circ \text{C}.$, this is a white solid which has a vapour pressure of about 0.75 mm.; (3) carbon dioxide coming from the atmosphere; (4) nitrous oxide; (5) nitrogen trioxide and peroxide; (6) sulphur dioxide; (7) sulphur trioxide and the vapour of sulphuric acid. These latter substances 3–7 are all non-volatile solids at $-189^\circ \text{C}.$, and therefore it should be easy to separate them at that temperature from nitrogen, oxygen and nitric oxide by pumping away these three gases by means of a mercury pump. By this method, of course, the nitric oxide would be lost; but it seemed worth while to carry out a few experiments to determine the amounts of the other oxides of nitrogen which were present in the flue gases. In order to test the method of separation, a quantity of air containing a known amount of nitrous oxide—the most volatile of the other oxides—was passed through a glass spiral which was cooled to $-189^\circ \text{C}.$, by immersing it in liquid air. This spiral could be evacuated by means of a Töpler pump; and, after the whole mixture had passed through it, the spiral was evacuated, thus leaving only the solid nitrous oxide behind. The liquid air was then removed and the nitrous oxide pumped off and collected. Its volume was then measured and compared with the volume taken. Two results, which are given in Table I., show that the amount of nitrous oxide lost is not more than 0.003 per cent. of the whole volume fractionated. Hence this method should give almost the whole of the nitrous oxide, &c., contained in the flue gases.

Table I.

Vol. of air used.	N_2O taken.	N_2O found.	Vol. per cent. of N_2O lost.
1000 c.c.	1.81 c.c.	1.83	0.003
1200 c.c.	1.44 c.c.	1.42	0.002

* Mr. E. C. Thompson has kindly checked this calculation by direct measurements made on a sulphuric acid plant, and his figures agree fairly closely with this calculation.

The analysis of the mixture of substances which could be separated in this way from the flue gases still presented some difficulties. It was impossible to use aqueous absorbents until the sulphur dioxide had been separated from the nitrogen trioxide and peroxide so that this stage of the separation had to be done by means of a second fractionation. It was found that at -122°C . the melting point of crude ether, only the nitrous oxide and carbon dioxide were volatile, so that these two could be separated from the other bodies at that temperature. At -95°C . the sulphur dioxide begins to distill over, and at the same time nitrogen trioxide decomposes giving nitric oxide and peroxide, of which only the nitric oxide distills over. Hence, at -95°C . sulphur dioxide and nitric oxide could be pumped away from the peroxide and separated from one another by a second fractionation at -189°C . In this way, the flue gases were divided into the following fractions:—

1. Nitrogen, oxygen and nitric oxide.
2. Nitrous oxide and carbon dioxide.
3. Nitric oxide (from trioxide).
4. Sulphur dioxide.
5. Nitrogen peroxide and sulphuric acid, and possibly nitrosulphonic acid.

The analyses of these different fractions then presented no difficulty. Fraction (2) was measured, then mixed with oxygen (or air) and treated with caustic potash. (The addition of oxygen or air lowered the partial pressure of the nitrous oxide, and therefore lowered the amount dissolved by the potash.) The residue was then again fractionated at -189°C ., and the nitrous oxide thus obtained pure. It was then measured, and its volume deducted from the original volume, the difference being the volume of the carbon dioxide. Fractions (3) and (4) required only to be measured. Fraction (5) which was left in the spiral, after the fractionation was complete, was shaken with air and water, thus forming sulphuric and nitric acids. The solution formed was titrated with N/10 barium hydrate, and the amount of barium sulphate formed was determined gravimetrically. From the figures thus obtained, the amounts of nitrogen peroxide and sulphuric acid could be calculated.
